## IMPACT FORMATION OF THE MOON

SPECTROSCOPY

product review

## The last thing the world needs is something else that won't hold up.

They say nothing lasts forever. Which may not be entirely true.

Consider for a moment a lab balance like our METTLER PM.

It's built to be precise. (An ingenious feature called "electronic calibration" makes sure a PM is very precise.)

And it's built to be simple to use. (An even more ingenious feature called "DeltaTrac" helps you see what you're doing, making it very simple to use.)

Why do you suppose we give each PM such a rugged housing?

Or back it with more service than you may ever need?

Or why in the world do you think we subject it to over 100 hours of tests before you're allowed to subject it to one minute of use?

The truth is, we have a rough idea of what you'll eventually put a PM through. So simply try to put a PM through it first. To find out more, call us.

# METTLER

# We specialize in quality, custom peptide synthesis ... so you don't have to!

319

Our proprietary techniques enable MPS to supply you with all the custom peptides you need. For example, we can provide over 100 completely different 15-residue peptides in as little as three weeks. An analytical HPLC chromatogram is included with each peptide ordered.

MPS offers quality peptides with service we're sure you'll like. Call us with your questions or if you would like a complete price list.

MPS also provides a custom HF Cleavage Service and a unique HF Cleavage System.

#### COMPARE OUR PRICES

MPS is offering custom peptides at the extraordinary prices listed below.

10mer	\$400
15mer	\$550
20mer	\$800

Prices are based on 50mg of HF Cleaved Peptide. 4 to 6 weeks delivery, minimum order of 3 peptides or \$1000.

#### CAN YOU SYNTHESIZE PEPTIDES FOR LESS?

Before you buy an automated peptide synthesizer, you should consider the actual cost for in-house synthesis which includes the cost of reagents, personnel, service contracts, analysis, waste disposal, downtime and, of course, the initial cost of the synthesizer.

HPLCs of unpurified, HF cleaved peptides

## Successful amino acid analysis.

It begins over a cup of coffee or tea. Because first we need to talk. But not about model numbers and purchase orders.

We need to talk about what you want and need. About how you prefer to run your laboratory — philosophies, methodologies and procedures.

At first, you'll do most of the talking, while we listen. And learn. Then — and not until then — we'll recommend the best answer for your particular analysis needs.

You may need the superior quantitation and reproducibility of the classical ion exchange technique. Or the speed and sensi-

tivity of reversed phase. We offer them both.

For the flexibility of HPLC, we offer System Gold™, the Personal™ Chromatograph. And the System 6300 dedicated ion exchange analyzer for physiological and diagnostic applications.

Whichever your choice, we provide proven methods, too. Complete and *guaranteed*.

You see, we've been involved in automated amino acid analysis since Moore, Stein and Spackman pioneered it in 1958. So you can rely on us for in-depth applications and technical support. Anytime. All the time.

That's why you can trust our recommendation. But we won't recommend a thing until we sit down and talk. And listen.

Take the first step in successful amino acid analysis. Contact your local Beckman office in major cities worldwide. In the US, call 800/742-2345.

Beckman Instruments, Inc., Altex Division, 2350 Camino Ramon, P.O. Box 5101, San Ramon, California 94583.

# DNA PROBES

(From the people who gave you Designer Genes™)

## Human Interleukin 1 $\alpha$

IL-1 $\alpha$  is one of the two major forms of IL-1 identified. Probes are available for Exon 5, 6 and 7 of the IL-1 $\alpha$  gene.

## Human Interleukin 1 $\beta$

The other major form of IL-1. Probes are available for Exon 5, 6 and 7 of the interleukin 1 $\beta$  gene.

## Human Interleukin 2

Interleukin 2 is a central factor controlling proliferation of T cells. Probes are available for Exon 1, 2, 3 and 4 of the IL-2 gene.

## Human Interleukin 3

IL-3 is a growth and differentiation factor for multipotent erythroid and myeloid precursors. Probes are available for Exon 1, 2, 3 and 5 of the IL-3 gene.

## Human Interleukin 4

With exon boundaries not yet fully defined for the IL-4 gene, probes have been designed for the 3' region, mid-region and 5' region of the IL-4 gene.

## Human Interleukin 5

Interleukin 5 is identical to B cell growth factor II. Probes are available for Exon 1, 2, 3 and 4 of the IL-5 gene.

## Human Interleukin 6

Interferon $\beta$ , hybridoma growth factor and BSF-2 are now known to be interleukin 6. Probes are available for Exon 2, 3, 4 and 5 of the IL-6 gene.

## APPLICATIONS

Designer Probes™ from British Bio-technology recognise certain unique exons of genes coding for interleukins. As the probes are based on the antisense sequence they are also suitable for detecting the corresponding regions in mRNA. These probes are single-stranded, chemically synthesized and supplied ready purified with recommended protocols for labelling. The probes are of defined length and T<sub>m</sub> and are suitable for the following applications. \*Northern and Southern Hybridisation \*Colony & Plaque Hybridisation \*In situ Hybridisation \*Dot-blot & Cytodot Hybridisation.

## PROBE COCKTAILS

Exon specific Designer Probes™ allow the identification of particular gene regions. The exons selected are all contained in the region coding for the mature forms of the proteins. Also available are Probe Cocktails which consist of an equimolar mixture of exon specific probes. Probe Cocktails will pick up a combination of different regions of the gene and therefore show a higher level of sensitivity than individual probes. Probe Cocktails can be used for all the applications listed above.

# nature

2 March 1989

Vol. 338 Issue no. 6210

The unusual orbital characteristics of the Earth-Moon system can be explained if the Moon formed from the debris of a collision between the early Earth and a Mars-sized body. The cover shows four stages in a computer simulation of the collision. See pages 29 and 19.

## THIS WEEK

### Last fall's drought

The 'greenhouse effect' was thought by some to be responsible for last year's US drought. But a complex global weather-prediction model links the drought to sea-surface temperature anomalies — one factor being the arrival of exceptionally cold water in the tropical Pacific. Pages 54 and 15. Congress takes steps, page 3

### Diabetes insight

The cloning of the gene for the insulin-regulated glucose transporter of adipose and muscle tissue could lead to new insights into non-insulin-dependent diabetes mellitus, page 83.

### Out of order

Muon spin rotation studies of a recently discovered electron-doped copper oxide superconductor reveal that the material's static magnetic order decreases with temperature and is totally destroyed when it becomes superconducting — as in hole-doped superconductors, page 49. Patents scramble, page 5

### Retinal decay gene

The characterization of a gene encoding a form of hereditary retinal degeneration in the mouse may make it possible to identify the cause of some cases of hereditary retinal degeneration in humans, page 70.

### Yeast recombination

Genetic studies in the yeast *Saccharomyces cerevisiae* have led to the identification of a chromosomal site for the initiation of homologous recombination. Both DNA strands at this site are cut during meiosis, supporting one current model for the mechanism of homologous recombination. Pages 35, 87 and 14.

## Political birds

The white-breasted guineafowl is but one of Africa's rare birds. Its extinction may be hastened by

Martin Woodcock

the exclusion of South Africans from the Pan-African Ornithological Congress. Commentary by T. M. Crowe, page 11.

## Fuelling the galaxies

Active galactic nuclei are usually thought to be powered by accretion onto a supermassive black hole. A mechanism for fuelling the nuclei, which relies on a 'stellar bar' instability sweeping the host galaxy's interstellar medium inwards, is described on page 45.

## One and the same

A *Drosophila* gene originally recognized by the effect of its mutation on visual transduction encodes a product closely related in sequence to cyclophilin, a mammalian protein that binds the immunosuppressive drug cyclosporin A. This is particularly intriguing in the light of the recent discovery that cyclophilin is identical to prolyl isomerase, an enzyme that facilitates protein folding. Page 67.

## Uranium frenzy

A compelling tale of the modern American West is the subject of a book review by Daniel J. Kevles, page 25.

## Guide to Authors

Facing page 29.

## M U L T I L U M I N E S C E N C E

The optimal combination of hardware and software makes this instrument suitable for fast and slow luminescent reactions. The highly sensitive, fast photon counting system enables the measuring of low as well as high light intensities.

A special, temperature controlled multiple measuring chamber, allows the measuring of 6 samples in time intervals of 1 second repeatedly and under identical conditions.

High precision is provided by «High Speed» Hamilton injectors. The integrated personal computer guarantees data processing with efficient graphics within seconds. Special user programs for phagocyte mediated luminescence, LIA and ATP make this instrument the ideal partner for routine and research.

# The Simple Solution

FOR YOUR DIFFICULT SAMPLES.

## A Beckman DU® Series Spectrophotometer.

Now even hard to handle samples can be analyzed with confidence quickly and easily using a Beckman DU® Series 60 or Series 70 Spectrophotometer. Beckman's exclusive Stable Beam Technology provides optimum performance with its high intensity focused sample beam, so that you can realize the greatest accuracy and sensitivity for your difficult samples without special apertures or cumbersome focusing and alignment procedures.

### Precise Microvolume Sampling

Analyze samples less than 50  $\mu$ l using Beckman's exclusive Five Carat™ microcell sampling system. When performing nucleic acid and protein analyses, this system allows you to recover virtually all of your precious samples.

### High Resolution Gel Analysis

Why buy a costly dedicated gel scanner? The DU® Series 60 and DU® Series 70 spectrophotometers offer the highest performance in gel and film studies—with resolution of data better than 0.1mm. Even hard to handle samples such as electrophoresis gels, photographs and 35mm slides of gels, or popular downsized gels can be simply and easily analyzed with calculation of molecular weights.

### Turbid Samples

To optimize energy collection from turbid or highly scattering samples, the DU® Series 60 positions the sample an ideal distance from the detector for maximum sensitivity.

### Control Sample Delivery, Data Acquisition and Data Output Format—at the Touch of a Button.

Customize your DU® Series spectrophotometer with special applications software for automated data computation and control. Software programs are available for microvolume samples, gel scans, nucleic acid and protein studies—and more.

## MicroSelect. Well Defined Standard

Ask for your free copy of the Fluka MicroSelect brochure.

"MicroSelect" Basics for Biochemistry is Fluka's newest line of high purity reagents designed for applications in the life sciences. All MicroSelect products are specified, tested and guaranteed to a wide range of parameters and are detailed in the brochure.

Guanidine thiocyanate is a typical example: It can be found on page 85 of the MicroSelect brochure.

Fluka's commitment to quality comprises a clear definition and a guarantee that follows each MicroSelect product, even on its label.

Moreover, the MicroSelect brochure contains considerable information covering applications, properties and characteristics, literature specification and references describing the most important techniques. The brochure also includes

many tables detailing stability constants, pKa values, buffer compositions, diagrams and charts, which makes the brochure a useful source of practical and theoretical information for every laboratory.

The Fluka "MicroSelect" programme includes

- Ammonium, calcium, cesium, lithium, magnesium, potassium and sodium salts
- Biological buffers, buffer components and standard buffer substances
- Precipitation and denaturation reagents
- Chelators and complexing agents
- Antioxidants
- Density gradient centrifugation chemicals
- Amino acids

# New membrane technology replaces classic column chromatography.

Now chromatography  
is as easy as  
sample filtration.

## Unique membrane allows chromatography without the column.

There's nothing remotely like the new porous Bio-Rex® chromatography membranes from Bio-Rad. These membranes consist of 90% chromatographic media in a web of PTFE, which results in high capacity and high flow rate.

As the electron micrograph shows, these membranes provide a new support system for column chromatographic media. Because the membranes are porous, they allow **simultaneous** separation and filtration, saving you valuable time. And you can forget about column packing and filtering resin beads, saving even more time!

The Bio-Rex chromatographic membranes are equally effective for both batch and flow-through processes.

At a glance:

- High capacity, high flow rate
- Results equivalent to packed columns
- Resistant to organic solvents
- Choice of three ion exchange membrane types — strong anion, strong cation, and chelating
- Available in free membrane or sample preparation disc form
- pH stable 1-14

An alternative to traditional column chromatographic methods, these convenient, easy-to-use membranes will save you time, effort, and expense. Find out more. Call 800-843-1412 and request Bulletin 1428.

# The outer limits in gel filtration

Sephacryl® High Resolution (HR) from Pharmacia LKB is a new range of gel filtration media for Standard Chromatography, and is already receiving world-wide acclaim from the research community. Now, we are introducing Sephacryl S-100 HR and S-500 HR to extend even further the molecular weight limits of the existing range – S-200 HR, S-300 HR and S-400 HR.

With new Sephacryl S-100 HR, you can separate biomolecules with MW from only a few thousands, such as peptides and small proteins. At the other end of the scale, new Sephacryl S-500 HR can separate very large biomolecules and small particles with MW up to about eighty million.

Both these new gels have steep selectivity curves and the other superb features of the HR range.

All the gels have excellent flow properties – a product of the balanced particle distribution (25–75 µm) – and won't generate high back pressures.

All the gels are easy to pack and easy to run. Their preswollen matrices tolerate high flow rates at any scale, from laboratory to industrial. And Sephacryl HR media are compatible with FPLC®.

All the gels withstand commonly used denaturing agents and detergents, and can be autoclaved or cleaned in place with sodium hydroxide; a consequence of their in-built chemical- and physical resistance.

Reach for the outer limits and order your gels today. Or ask your representative for the new Data File.

# GET THE KNOWLEDGE YOU NEED

March 28-30, 1989 • Hyatt Regency

- The significant research
- The newest methods
- The latest products
- The notable experts
- The industry contacts
- The financial synergy
- The international perspective

AgBIOTECH '89 features a multi-track professional seminar program that only the editors of BIO/TECHNOLOGY could produce. And it's *all-ag*, all aspects — from lab to production to marketing to regulation.

## Science/Technical

You'll hear leading researchers responsible for the most significant and splendid advances in transgenic crops and genetic engineering techniques discuss their research.

## Business/Regulatory

You'll hear experienced industry executives with in-the-trenches experience discuss what has worked, what is economically viable, regulation, patenting, and future development.

If you're in ag-biotech — and determined to stay competitive in the '90's — you can't afford to miss this stimulating program! REGISTER TODAY!

## A Faculty Of More Than 75 Ag-Biotech Experts Including:

Gordon Ada, Johns Hopkins University  
 \*Charles Arntzen, Texas A&M University  
 \*Harvey Bialy, Bio/Technology  
 Charles Baker, BioTechnica Agriculture  
 Andrew Barnes, Mycogen

## Bush badly needs good advice

President George Bush has promised to create better machinery for gathering technical advice, but time is passing. A search for a paragon should not let him hide from the urgency of his need.

THE new president of the United States may be saying all the right things (see *Nature* 337, 585; 1989), but he is doing fewer of them than he should. This complaint has been levelled generally at the new administration, which has yet to fill its roster of cabinet appointments, let alone all the second-rank posts, all of whose incumbents will have to be interviewed by a committee of the Senate and judged capable of doing their jobs. But the complaint is particularly apt when applied to President Bush's plans for the more effective administration of science, among the most ambitious of those put forward last month.

Briefly, Bush would give a new science adviser the status of "assistant to the President", putting him or her on a par with the head of the National Security Agency (now General Brentt Scowcroft). On top of that, there is to be a Council of Science and Technology Advisors resembling in all but name what used to be the President's Science Advisory Committee (PSAC), much respected until killed off by President Richard M. Nixon. But nobody has yet been nominated for the top job. Even if a name should have appeared before the end of this week, a quarter of a year (or a sixteenth of a presidential term) will have gone before the man or woman can set to work.

The administration's general excuse for its tardiness — that its succession of the like-minded Reagan administration means fewer policy discontinuities and thus a lesser need of new officials — does not apply to the science advisory job which, as advertised, is an innovation. The present holder of the office, Mr William Graham, has had only meagre influence during his two years, and is unlikely to be struggling for promotion.

So why not pick somebody and get on with it? The word is that the administration is looking for a science adviser from industry, which is consistent with the Bush view of science as a means of improving the competitiveness of the United States in the "global marketplace". One snag is the formidable list of loyalty tests the new incumbent will have to survive: finding a Republican will be easy, finding somebody willing to go to the stake for the Strategic Defense Initiative will be something else.

A more practical difficulty may be that there is already a technical person powerfully placed at the White House. Mr John Sununu, Bush's chief of staff, was a chemical engineer before becoming governor of New Hampshire. Between gaps in what must be the fullest appointments diary in the Western world, not to mention side-trips to

Japan, China and Korea, Sununu is interviewing potential candidates for the new job. Quite apart from his lack of time, there may be a further difficulty: some putative incumbents may be deterred by knowing that the man who allocates space in Bush's working day is likely to have his own strong views on what science advice the president should be given.

Yet the need for an appointment becomes more urgent every day. In just over two months, the National Security Council is to have completed a review of US policy on national security, to which an able science adviser would have a powerful contribution to make.

Soon afterwards, early in the summer, there will be a ministerial meeting of the North Atlantic Treaty Organization that will be crucial for the future of US weapons policy. Meanwhile, the administration is being challenged by the daunting character of its own agenda (improving public education, doing something effective about AIDS and drugs) as well as by the conundrums thrown up by the Congress, the still-unfocused worry about climatic change for example (see page 3). The danger is that too many of these issues will be decided by default.

The reconstitution of PSAC will raise other problems. From its creation after the Second World War until its abolition, the old PSAC won respect by the self-evident independence of its members. Sometimes it could be an irritating talking-shop, but its strength was its readiness to oppose administration policy when it thought fit. Bush is looking for a council of "leading scientists, engineers and distinguished executives from the private sector" (which includes the universities), which is not in itself a bad prescription. But will he allow that the advisers should be chosen for the calibre of the advice they have to offer, not the likelihood that the advice will be acceptable? That will be the acid test of whether Bush means all the right things he is saying. □

## Science squeezed

Nobody should be surprised that ten years of short commons have deprived Britain of researchers.

THE emergence in Britain of a shortage of young researchers (see page 7) is about as remarkable as the diurnal rhythm. For close on ten years, British research

establishments have been harassed by lack of funds, so that newspapers have been full of tales of researchers who have been put out to grass or who have fled abroad. Young people, who read the newspapers, have also learned from them that entrants to other professions, that of providing financial services, for example, are likely to live more prosperously, and have voted with their feet. That there is a shortage of putative graduate students is not in the least surprising, but a predictable consequence of the market forces on which the British government bases most of its policies, sometimes successfully. It is even more worrying that the past few years have probably frightened away an unduly large proportion of the most able people.

There is now no quick remedy. The Medical Research Council's plan to offer graduate students on its books an extra £500 a year, commendable enough, is about as relevant to the underlying market forces as would be a great man's attempt to interfere with the diurnal tides by walking into the sea (which is what King Canute demonstrated nine centuries ago). Even doubling the present meagre stipend would have little beneficial effect. Only when the practice of research in Britain has been shown again to be an honoured as well as an honourable profession will young people be clamouring for the studentships on offer.

That calculation should be central in the planning of how to spend the extra sums for research now being made available. But that appears not to have been the case. Too much of the extra is being spent on directed research or, worse, on the research councils' own establishments, too little on the means (research grants) by which individuals might make a mark and thus fire the imagination of young people choosing a career. Researchers should fight to see this balance redressed, knowing that in doing so they will be serving the wider British national interest.

Meanwhile, as a stop-gap remedy, the research councils might think of offering their studentships to young people from abroad, coupled with work permits to stay in Britain permanently. In the United States, for different reasons afflicted by a shortage of young researchers, the stragem works well enough. □

## Satanic violences

The Shiite threat to kill a British author and the violence of animal rights extremists have a lot in common.

MR Salman Rushdie's book *Satanic Verses* opens with the fantasy of how two unremarkable people survive the destruction (by a bomb) of an aircraft over the English Channel and then found a new religion. The ways of the Shiite Muslims who have now offered a money prize for Rushdie's assassination and those of the people who advocate civil rights for animals may seem only remotely connected, but they are nevertheless worth remarking.

Apart from the bomb last week at the University of

Bristol (remarkable only for being the first use of high explosives to damage British property in this particular cause) and the occupation of a crane on a Berkeley construction site, this has been a relatively quiet week, yet in their character the protests on behalf of animals have precisely the qualities that make the threats against Rushdie as offensive as they are.

First, it must be clear that the Shiite threat is an act of violence. One apologist last week is quoted as saying that "the arrow . . . is already travelling to his heart", by which is presumably meant that the threat will be regarded for decades to come as an invitation to some impressionable assassin to push the arrow home. The more tangible violence of the extremists in the animal rights movements has the same implacable quality; nothing, especially not reason, can divert it. It has the same quality of detachment from the identities of those who are injured; Shiites imprison random Western travellers to Beirut for years on end, while the explosion of a bomb at the University of Bristol is similarly random (but there is a veterinary school there). Why pick on that rather than on some other British university? Because it happened to be handy, perhaps?

As with the case of Rushdie so on the animal rights front, the most urgent need is that the moderates who believe that Rushdie's book is blasphemous (to Muslims) or that animals are misused in research should clearly dissociate themselves from the actions of the extremists. At least in the use of animals in research, the moderates have a powerful case, not least in their demands that people's use of animals should be as sparing as possible and that humane procedures should be followed. Failure to condemn these acts of violence has two consequences; the extremists are excited, while the moderate case is so tarnished by its association with violence that it is dangerously weakened. Sadly, that lesson seems not yet to have been learned, either in the case of Rushdie's book or that of the bomb at Bristol. □

## Unfamiliar disguises

The unfamiliar appearance of this issue of *Nature* implies no systematic change of content.

REGULAR readers who happen to notice the typographical changes in this week's format will passionately resent the small changes which have been made. That at least is what past experience shows. The only comfort is that, with the passage of a few weeks, the same readers will become just as vigilant in the defence of what is now offered — a layout which is generally more uniform, in particular respects more workable and which may help to make some sections of *Nature* more readable. No attempt has been made, on this occasion, to introduce fancy typographical tricks or even to restore the couplet from Wordsworth's "Endymion" from which this journal's name was taken in 1869. □

# US Congress plans greenhouse legislation

- Tough measures on global warming
- Scientific opinions differ

## Washington

THE new US Congress has begun with a stampede by legislators introducing bills meant to respond to the perceived threat of global warming. But researchers at congressional hearings last week seemed much more cautious than the legislators in estimating what the future holds for the world's climate.

Several wide-ranging bills on global warming have been introduced since the Congress opened on 25 January. The most recent, the "Global Warming Prevention Act of 1989", was announced by Claudine Schneider (Republican, Rhode Island) of the House of Representatives on 21 February, and has 50 co-sponsors.

Schneider's bill embodies many of the elements of those launched a few weeks ago by Senator Timothy Wirth (Democrat, Colorado) and Senator Albert Gore (Democrat, Tennessee). It calls for an international agreement on a 20 per cent reduction in global carbon dioxide concentrations by the year 2000 and the revision of the Montreal Protocol to phase out all chlorofluorocarbon production within five to seven years. Under the legislation, US aid for family planning services in developing nations is doubled to help reduce population growth (and hence energy demand) and recipients of foreign aid will be required to practise sustainable forest management. Tropical timber imports will be banned from countries that do not comply.

On the domestic front, the bill would provide hundreds of millions of extra dollars for research and development on energy-efficient technology, solar and renewable energy resources and solar-generated hydrogen fuels. There would be tax rebates for fuel-efficient cars, and increased 'gas guzzler' taxes.

The drive to legislate stems from widespread public concern about global warming, and the greenhouse effect. The issue caught the attention of the media during last summer's drought in the United States. But, ironically, few if any researchers attribute the drought to the greenhouse effect. Stephen Schneider of the National Center for Atmospheric Research (NCAR), giving evidence to the House of Representatives' subcommittee on Energy and Power last week, said it is "absurd" to suggest a direct causal link. But he welcomes the attention global warming is receiving in Congress even if it is "for the wrong reasons".

NCAR's Schneider strongly suspects

that the high average global temperatures of the 1980s, which are about half a degree Celsius higher than at the end of the last century, are a greenhouse signal; he advocates action now instead of later.

But Robert Correll, of the National Science Foundation, in evidence last week to the Senate Commerce, Science and Transportation Committee, noted that the increase of temperature over the past century has not been steady, in contrast to model predictions of the greenhouse effect. And Correll says that the current differences of opinion among scientists as to whether there is now a greenhouse

warming are "substantial".

Some members of both committees seemed irritated by the lack of consensus and warned the scientific witnesses that their uncertainty might be used by some congressmen as an excuse for no action.

Regardless of uncertainty, opposition to the new legislation is bound to be strong. The powerful automobile industry will oppose legislation that favours more fuel-efficient imports, and the coal industry will object to action that might substantially reduce coal consumption. The new bills are expected to have a particularly rough passage through the Senate Energy Committee, where these interest groups have a strong voice. But there is considerable public pressure on Congress to "do something", and if the heat waves strike again this summer — particularly if they strike Washington — it is almost certain that some of the new legislation will be passed.

## US REACTORS

# Shoreham plant to be revived?

## Boston

NEW YORK's never-licensed Shoreham Nuclear Power Station may be rising from its grave, if its parent utility's stock is any indication. The stock of the Long Island Lighting Company (LILCO) has recently been the third most actively traded of the stocks, on the New York Stock Exchange.

The speculative flurry has been caused by two developments in the tangled but continuing saga of the nuclear plant. A federal judge has thrown out a case brought by the local legislature which accused LILCO of "racketeering" and corruption, and the US Nuclear Regulatory

also have raised electricity rates, even though it would have restricted the utility's right to pass on costs to ratepayers (see *Nature* 333, 588; 1988).

The plan was sanctioned by all the major parties involved, but was derailed unexpectedly when the New York State legislature refused to ratify it out of fear of political reprisals.

Ironically, Long Island constituents, whose electricity rates are already the second highest in the United States, will now face even greater cost increases, whether or not the plant goes into operation.

There are still many hurdles ahead for the Shoreham reactor, most notably the strong local and state-based political opposition.

Shoreham's local Suffolk County legislature voted unanimously to appeal against the rejection of its racketeering and corruption suit against LILCO, turning down a settlement of nearly \$400 million offered by the utility in reduced electric rates. The legislature said it would not settle the case unless the utility promised that it would "irrevocably close, shutdown and decommission" Shoreham.

But despite their differences, all the parties involved agree that Shoreham's fate is highly uncertain. Even LILCO representatives say that they are now following a "two-track" strategy: moving ahead to license the reactor, and trying to negotiate a scheme to shut the plant down. What they find intolerable is the waiting and indecision, which they claim has cost the utility \$1,700 million in interest and finance charges since the plant was completed.

Seth Shulman

Commission is expected to rule soon upon whether to grant the Shoreham reactor a low-power operating licence. Both developments promise a future for the power station, which was completed four years ago.

The Shoreham plant was widely pronounced dead last spring, when New York State authorized a plan to close and decommission the reactor, but which would

## UK ANIMAL RIGHTS

# University building bombed

## London

BRITISH police now fear a bombing campaign against other universities after the explosion of a bomb, thought to have contained 5 pounds of high explosives, in an administrative building of the University of Bristol last week. The bomb went off in the staff restaurant of the Senate House at midnight on Wednesday, 22 February. There were no casualties.

Responsibility for the attack has been claimed by the Animal Liberation Front (ALF), a well-known group of extremists, and by two previously unknown groups, the Animal Defence Organisation and the Animal Abused Society, which warned the police beforehand of the bomb. The ALF has usually concentrated its attacks on the houses of scientists, which have been daubed with paint, and on retail shops selling items such as furs.

The Secretary of State for Education and Science, Mr Kenneth Baker, visiting the university after the explosion, called the attack "an appalling example of terrorism". He said that tighter security might be necessary at British universities.

British animal rights groups have previously had some success with incendiary

Bomb damage inside the Senate House.

devices, but have not hitherto used high explosives. Animal rights groups which campaign using non-violent means against vivisection have condemned the bombing. A spokesman for the British Union for the Abolition of Vivisection says it will cause extreme damage to the campaign against animal experimentation. There are 50,000 members of non-violent groups, he says, and less than 100 in the loosely-organized group of individuals which makes up the ALF.

Christine McGourty

## US ANIMAL RIGHTS

# Activists setting the agenda

## Berkeley

THE divisive issue of the use of animals in research was the centre of attention last week at two San Francisco area universities. Stanford University has been debating a genteel change of policy that would affect the use of animals in teaching, while, on the University of California campus at Berkeley, a more acerbic debate over an animal care facility has flared up.

Animal rights activists have been stepping up their activities in California. Last week, six of them scaled a 175-foot crane at a construction site on the Berkeley campus to protest at the building of the

university's new animal facility. Unfurling banners that read "Stop Germ Warfare Lab!" and "No Toxic Animal Lab!", the protesters vowed to remain on the crane for two weeks. But university officials have called the stunt "ironic", because the crane is not involved in the construction of the new animal facility, but instead is being used to put the finishing touches to a plant-biology building.

The university is hesitant to remove the protesters, fearing that somebody would be hurt in the process. Construction of the animal facility has continued undisturbed, but the protest is costing the university more than \$10,000 a day, according to one spokesman, to pay for 24-hour security guards and lost construction time.

Meanwhile, in an effort to avert future animal rights controversies in the classroom, Stanford University has drafted a policy that would inform students which courses and degree programmes use animals in instruction. The new policy, now being finally revised, encourages students to raise with their instruc-

High-level protests against Berkeley's new laboratory.

## SOUTHERN AFRICA

# UCT again confronts government

## Oxford

THE University of Cape Town (UCT) is once again in confrontation with the South African government, this time because of a breach of confidence by the Minister of Health and Population Development, Dr Willie van Nierkerk.

The issue concerns Dr Jocelyn Kane-Berman, whom van Nierkerk sacked from her former post as superintendent of the Groote Schuur Hospital, UCT's teaching hospital, and the post of dean of the medical school at UCT, which the university is now seeking to fill against a pending retirement. In reply to parliamentary questions about the dismissal, van Nierkerk said that he would approve Kane-Berman's appointment as dean because, at UCT, she would be "in an environment where the proximity of the ANC (African National Congress) is well-known".

Apart from the slur on the university, UCT is incensed that van Nierkerk should comment publicly on one application for an academic post which is still under consideration. Van Nierkerk, a former professor of obstetrics and gynaecology at Stellenbosch, can hardly be ignorant of the niceties of academic appointments.

UCT now says that the insinuations in the minister's remarks are "disgraceful". Dr Stuart Saunders, the vice-chancellor, and Mr Leo Abrahamse, the chairman of the council, who met the minister to protest, said that van Nierkerk had chosen not to provide an explanation, and that the university would now be making representations through other channels.

The cause of Kane-Berman's sacking from Groote Schuur was her statement, to a weekend newspaper, that Nelson Mandela would be her choice as prime minister in a South African government chosen on merit (see *Nature* 336, 612; 1988). The *South African Medical Journal* has called for her reinstatement, but the minister is unrepentant. Meanwhile, Kane-Berman intends to sue her former employers, the provincial administration, for reinstatement.

Michael Cherry

tors any concerns they may have about animal use. But although it provides room for individual solutions, the policy does not oblige instructors to change course requirements.

Stanford spokesman Robert Beyers said the concept of forewarning students was stimulated by the passage in the state legislature last spring of a law that allows primary and secondary school students to refuse to dissect animals in the classroom.

The new rule may have little impact, because animals are rarely used in undergraduate courses, and no required courses in the medical school or the biology department involve animals.

Marcla Barlnaga

## SUPERCONDUCTOR PATENTS

# Four groups join battle

## Washington

THE US Patent Office is now wrestling with competing claims to patents on high-temperature superconductivity from four different research groups — at IBM, AT&T, the University of Houston and the US Navy. The patent office says there is a conflict over priority in the four claims to have discovered useable versions of the copper oxide superconductors. If the patents office can resolve the conflict, its decision could be a boon for the organization whose claim succeeds.

The conflict, legally called an 'interference' proceeding, has arisen because the patent applications by the four are similar, overlapping, and were filed at almost the same time. The parties to the dispute have each filed a string of patent applications for both the lanthanum copper oxide materials discovered in 1986 by Nobel prizewinners Georg Bednorz and Alex Müller, of IBM Zurich, and the yttrium-based copper oxides discovered by Paul Chu of the University of Houston and Maw-Kuen Wu of Alabama University in January 1987. It is widely believed that the yttrium compounds will have more general commercial application than the lanthanum materials.

The US Patent Office will have to decide not only whether patent applications for the lanthanum oxide superconductors can be extended to cover the yttrium compounds, but also whether applications based on mixed-phase materials of unknown crystal structure are valid (as in the case of Chu's first patent application for yttrium copper oxide material).

Information about patent applications for the superconductor materials began to come to light last summer, in Europe and Japan, where by law applications are made public 18 months after submission (or after the earliest priority date claimed). US patents are not published until granted, but several of the European and Japanese patent applications include priority claims for US patents and so disclose US filing dates.

The application from the US Naval Research Laboratory has not previously been known of, having been filed only in the United States. At the applications stage, even cases of interference are not publicized by the US patent office, but Cynthia Stevens, an IBM spokeswoman on patents, confirms the identity of the four competing applicants.

Japanese patent applications are notable by their absence in the dispute, in contrast with the common fear in the United States that Japan will be the first to exploit the commercial applications of the high-temperature superconductors. One explanation may be that the early patent applications by University of Tokyo

researchers are narrowly drawn and cover only the lanthanum oxides (see *Nature* **335**, 389; 29 September 1988).

Japan's Ministry of International Trade and Industry (MITI), which has filed broad applications worldwide covering the yttrium oxides, may claim interference at a later stage, according to Christopher Vear of the British Technology Group who is monitoring patent applications for the new materials. But MITI filed after the US groups in January 1987 and does not seem to have a strong position.

Japan's real strength lies in patent applications for devices made from the new materials and processes for making the superconductors into wires and thin films. Japanese companies, in particular Sumitomo Electric Corporation, have filed hundreds of such applications in Japan and many have been combined into broad patent applications in Europe, where Japanese interests have filed most applications. According to Vear's latest figures, Japan has filed 80 applications in Europe compared with 28 for the United States, 5 for West Germany, 4 for Britain, 3 for France and 1 each for the Soviet Union and Hungary.

The only patent so far granted has been awarded by the US Patent Office to John B. Vander Sande and Gregory J. Yurek at the Massachusetts Institute of Technology (MIT) for a process that combines the new ceramic materials with silver to make a more malleable material (see *Nature* **336**, 607; 15 December 1988). But soon after the award was announced, Sumitomo filed a claim for interference with a similar patent application it had filed within a day of the MIT researchers, according to Vear. Such claims of interference can be expected to multiply dramatically in the near future.

Patent interference cases in the United States can take years to resolve. One example is the battle over patent applications for the gas discharge laser, which took 28 years. The dispute over patent rights on high-temperature superconductor materials may become such a case because of the large number of parties involved. But a long legal battle could work to the eventual winner's advantage. If, as many experts predict, commercial applications of the new materials will not be feasible for at least a decade and because, in the United States, the life of a patent begins only after it is issued, the group to which the patent is eventually granted may enjoy licence fees for longer than if its claim had never been challenged.

**David Swinbanks**

■ On page 49 of this issue, the recently developed 'electron' superconductors show behaviour similar to the more established 'hole' superconductors. □

## NEWS IN BRIEF

## Personal communication

### London

THE Union of Scientists and Inventors' Societies of the USSR has established a special "international commission for relations with former compatriots", aimed at establishing links with Soviet scientists and engineers now working in the West. Such people have hitherto been regarded as ungrateful renegades, who have accepted the benefits of a Soviet education and then decamped to the capitalists. The new commission, however, considers them a potential channel for establishing closer cooperation between Soviet science and the West. Interviewed by *Sotsialisticheskaya Industriya*, commission member Academician Yuri Gulyaev suggested a whole range of ways in which the *émigrés* could help Soviet science, from taking Soviet graduate students into their laboratories for a year or two to organizing joint research groups. Many countries, Gulyaev said, gained considerably by working with their *émigré* scientists in this way — Hungary especially. "We have been accustomed to working only through official channels" . . . but personal contacts and informal links are sometimes more effective." V.R.

## Three per cent is six

### London

BRITISH universities will receive a 3 per cent increase in government grants for recurrent expenditure in 1989–90. The minister for higher education, Robert Jackson, announced that £1,680 million will be distributed to the universities in the next academic year, an increase of 6 per cent from 1988–89, but much of the increase included in the government figures is accounted for by costs for restructuring and agreed pay awards for previous years. The universities' vice-chancellors say the 3 per cent increase is too small, and have asked for an increase of 5 per cent. Jackson also said the universities should plan for an increase in 1990–91 of 4 per cent in cash terms and increases of 3 per cent in the following two years. C. McG.

## Chip complex destroyed

### New Delhi

INDIA'S microelectronics industry has been shaken by a fire that almost totally destroyed the \$100-million semiconductor complex in Chandigarh, the country's only facility for producing silicon chips for civilian needs. Sabotage has not been ruled out as the cause of the fire, which burnt down the entire complex, leaving only some design documents and the administration block. Mr Virendra Mohan, chief of the facility, has resigned after acknowledging moral responsibility for the accident. There are now fears that many of the nearly 200 engineers working at the Chandigarh complex and who are now out of work may migrate to the West.

India's semiconductor needs will now have to be met by imports or by setting up a new facility that will not be ready before 1992.

K. S. J.

## Oceanographers' lobby

Washington

To help convince Congress that oceanographers should play an important role in plans to address the issue of global change (see page 3), representatives from some four dozen oceanographic institutions met last week in Washington to form the Council on Ocean Affairs.

Jim Baker, president of the Joint Oceanographic Institutions, which has sponsored the new council, says that while federal agencies such as the NOAA and NASA are knowledgeable about the needs of oceanographers, Congress needs independently to be educated about the issues important to them.

While the council is intended to represent institutions, the new Oceanography Society, also promoted by Baker, is a professional society for oceanographers. The society will hold its first annual meeting this summer in Monterey, California. J.P.

## Staab steps down

Munich

HEINZ Staab, president of West Germany's Max Planck Society (MPS), has announced that he will resign when his six-year term ends in the summer of 1990. A newly formed selection committee will present a list of potential replacements to the MPS senate in November.

Staab, 62, who is also a director of the Max Planck Institute for Medical Research at Heidelberg, would have been eligible for one more term. He is stepping down to devote himself to research. S.D.

## Melbourne rivalled

Sydney

SYDNEY may be about to take a step to right the balance between itself and Melbourne, traditionally the centre of Australian medical research.

Professor Tony Basten has been appointed director of the new Centenary Institute of Cancer Studies and Cell Biology, a joint venture between the Royal Prince Alfred Hospital and the University of Sydney. The new institute will incorporate the Clinical Immunology Research Centre at the University of Sydney and is due to move a staff of 150 to two floors of a new six-storey building by October 1990.

The institute will be supported by state and federal grants, a block grant from the National Health and Medical Research Council and money from the private sector. T.E.

## Genentech's heart drug

Washington

THE US Food and Drug Administration ruled on Monday of this week that Genentech can claim in its advertising that TPA (tissue plasminogen activator) reduces the death rate among patients experiencing a heart attack, based on new data from two ongoing clinical trials comparing several heart drugs. Previously, the agency would only allow that TPA treatment dissolves the blood clots causing the heart attack. C.E.

# Freeze hits BMFT research

Munich

BATTLE lines have been drawn for the fight for next year's budget for the West German Research and Technology Ministry (BMFT), with European space projects, microelectronics and other politically sensitive items hanging in the balance. The federal research minister, Heinz Reisenhuber (Christian Democrat or CDU), has even come under attack from his own party as well as the opposition for not fighting harder for an increase in his stagnating budget.

BMFT is responsible for the general promotion, planning and coordination of research in West Germany. It supports technological research and development, data processing, nuclear research and technology as well as space and aeronautical research. As well as providing the lion's share of support for the Large Research Establishments (*Grossforschungseinrichtungen*) and the Max Planck Society, BMFT supports basic research at universities in selected areas.

The BMFT budget will decrease in real terms in 1989 for the first time in recent memory, if a budget freeze imposed last November is not lifted. The ministry lost DM190 million of its DM7,600 million budget to a "global reduction" imposed on all ministries. A further DM166 million has been frozen by the finance minister. Coupled with the effects of inflation, these cuts result in a reduction of the overall amount spent by BMFT in 1989, instead of the 2.8 per cent increase announced last year.

Ministry officials are not optimistic that the freeze will be lifted, but are trying to estimate where the axe will fall. A likely candidate for a cut would be the West German contribution to the large projects of the European Space Agency (ESA). But ESA would have to approve any such reductions, the effect of which might be to delay projects such as the space shuttle Hermes or the booster rocket Ariane 5.

The Max Planck Society, 60 per cent of whose funds derive from BMFT, will be largely protected from the cuts, thanks to the efforts of the West German finance minister Gerhard Stoltenberg and the *Länder* (states).

The shape of the 1990 budget will emerge in the next few weeks from discussions between BMFT and the Finance Ministry. The government will present a budget to parliament only in July, after its broad scope has been decided behind closed doors.

Meanwhile, there are signs that the ministry will shake off its lethargy and, even at this stage, ask for a big increase in 1990, partly to make up for the cuts in

1989. A ministry spokesman would not say how big an increase Reisenhuber will seek, except to say that it will be more than the growth of the overall federal budget. Some predict that the minister will ask for an extra 6 per cent.

West German participation in Hermes and the space station Columbus has begun to look even less certain than before in the light of the struggle over the BMFT budget. The consensus in Bonn is that it will probably not matter if a few tens of millions of deutschmarks are delayed until next year. But a much bigger commitment will be necessary in 1991 if Hermes and Columbus are to get off the ground. So far, the money required, eventually amounting to thousands of millions of deutschmarks, has not shown up in the medium-term West German budget.

In a related development, the Bundestag budget committee voted last week to release a previously frozen DM27 million for supersonic transport technology. The money will be invested in developing the proposed West German space plane Sänger, which represents the next generation of space shuttle technology.

Yet West German research and development continues to grow. But figures made public by BMFT show that the rising investment in West German research and development derives primarily from industry. No less than 74 per cent of the

Heinz Reisenhuber (right) is under pressure from his own party and the opposition. Social Democrat member Josef Vosen complains "Reisenhuber has promised a lot, but the money is not [yet] there".

DM61,400 million spent in 1988 was industry money. But a BMFT official says it is "questionable" whether overall research spending will continue to grow as fast as the gross domestic product, given the slow growth in the BMFT budget and the loss in 1990 of tax deductions for some company research.

BMFT notes that the trend elsewhere, in Japan and the United States for example, is just the reverse, with governments spending "disproportionately much" on research. But a BMFT official adds that there has recently been a "storm" of grant applications from university researchers, suggesting that the stiff competition for grants experienced by the Deutsche Forschungsgemeinschaft (DFG) has now hit BMFT as well (see *Nature* 337, 590; 16 February 1989).

Steven Dickman

## SWISS RESEARCH

# OECD urges changes for 1992

## Munich

SWEEPING changes in science and technology policy will be required if Switzerland is to meet the challenge of the internal European market planned for 1992. That is one conclusion of a report\* released by the Paris-based Organisation for Economic Co-operation and Development (OECD) in Berne this week. The review was carried out at the request of the Swiss government.

The survey team of three international examiners based their report on a series of site visits to Swiss laboratories, universities and public and private institutions.

The recommendations urge changes in policy at federal and cantonal levels as well as in universities and in industry. The reviewers found a "distressing" lack of cohesion in national science policy, with a resulting parochialism and slowness to change. Such traits may leave Switzerland "almost isolated in Western Europe" given the country's decision to remain outside the European Community (EC).

The most striking recommendation is the creation of a "secretary of state" for science and technology in the Federal Department for Home Affairs. This official would coordinate federal and cantonal policies as well as Swiss participation in international programmes.

The OECD report encourages Switzerland to invest more in research and to do so more effectively. In spite of being the richest of all OECD member countries, the report says that "public resources for research do not match those of most other OECD countries". The high percentage of the gross domestic product invested in research comes about because of research-intensive pharmaceutical and electro-mechanical industries. OECD strongly recommends that the Swiss government streamline the diffuse structure for research policy-making and establish a "national research budget" — at present decisions are made at a local level in the departments.

The lack of major public research institutions (with the single exception of the Paul Scherrer Institute for nuclear research) comparable to those elsewhere in Europe gives the team the impression of "weakness, dispersal and fragmentation of public R&D funding," said OECD.

Among the new programmes recommended by OECD are "substantial" national research programmes in information technology, new materials and biotechnology. The lesson learned when Switzerland "missed the turning" on the electronics road — and failed to develop an indigenous industry in digital watches or other electronic products — must not

be forgotten, warned OECD.

OECD concurred with some university researchers and industrialists (see *Nature* 336, 331; 24 November 1988) that Switzerland needs a publicity campaign explaining the benefits of science to the public and to school leavers. Distressingly few Swiss students are studying science and engineering, raising doubts about the future supply of skilled personnel.

On the Swiss National Science Foundation, which supports much of the basic research at Swiss universities, the report called "unhealthy" the practice of reducing individual project allocations by up to 30 per cent to allow more proposals to succeed. This encourages groups to submit inflated grant proposals and can prevent some projects from achieving "critical mass."

## RESEARCH COUNCILS

### MRC offers more

#### London

THE British Medical Research Council (MRC) wants to increase the pay of graduate students in the hope of stemming the growing shortage of young researchers. Last week, the council asked the Department of Education and Science (DES) to allow an increase from just under £3,000 to £3,500 in the stipends paid to the holders of its basic research studentships from next September. In doing so, the council is planning to break with the traditional method of calculating graduate students' pay using a DES formula linking it with the maintenance grants for which undergraduates are eligible.

The council also wishes to offer an extra £500 a year to graduate students working on its directed AIDS programme of research, which would be the first time that pay differentials not based on location had been offered. The stipends paid to holders of research council studentships are usually tax-free.

The problem of attracting talented young researchers is also worrying the Advisory Board for the Research Councils. At a meeting organized by the Royal Society last week, ABRC chairman Sir David Phillips said that the shortage of research manpower would be the most serious problems the research councils would have to face in the 1990s.

ABRC's Biotechnology Advisory Group is now urging the board to set up a formal review of the manpower shortage and to suggest ways in which it might be remedied. One member of the group, Professor Peter Dunhill of University College, London, says that if nothing is done about the shortage, all the councils' initiatives in biotechnology could fall apart.

Christine McGourty

The report repeats the commonly voiced fear that, without subsidies, the small and medium-sized companies forming a large part of Swiss industry will not be able to compete with their rivals in EC countries.

Rounding out the OECD recommendations is a list of conditions to be met if Switzerland's "production apparatus" is to face the needs of modernization. The list was first prepared by the Battelle Institute in 1983 in a study of what had gone wrong with Swiss industry in the 1970s. The Battelle Institute said Swiss industry should take more risks in introducing new technology, that large and small companies should cooperate more closely, and that the banks should take a greater interest in the promotion of new technology. OECD said that the recommendations are "still valid today."

Steven Dickman

## NAGYMAROS DAM

### Objectors find a voice

#### London

THREE members of the Hungarian National Assembly are in danger of losing their jobs because of their electors' objections to the controversial Gaboikov-Nagymaros hydroelectric scheme. After a majority of the assembly voted for completion of the Hungarian part of the scheme, three constituencies (two in Budapest and one in Szeged) have voted to recall the mandates of their representatives under a previously unused provision of the Hungarian constitution.

The decisions reflect growing opposition in Hungary to the Nagymaros dam, part of a joint project with Czechoslovakia. There are demands that the government should annul its treaty obligations to Czechoslovakia (as well as the construction debt to Austria), and that Hungary should pull out of the scheme unilaterally.

The decisions also reflect a new political awareness in Hungary. In a one-party system (as at present), the right of recall is a guarantee that constituents' views will be accurately represented in the assembly. (A fourth deputy is threatened with recall for reasons unconnected with the dam.) But there are signs that the ruling Socialist Workers' Party may abdicate its monopoly; the Central Committee has now accepted the principle of a multi-party system with appropriate "checks and balances".

But whether this will allow the emergence of a 'green' party in Hungary is uncertain. Janos Vargha, one of the leaders of the 'Danube circle' which has campaigned against the dam told a recent conference of environmentalists that a green party could compromise the independence of existing groups.

Vera Rich

\*Reviews of National Science and Technology Policies: Switzerland. The report, including an account of the review meeting held in Berne on 3 March, will appear in book form later this year.

## REMOTE SENSING

## European satellite reception

### Paris

THERE is now hope that the European Remote Sensing Satellite, ERS-1, to be launched next year, will have an enthusiastic band of users. That seems to be the outcome of last month's meeting between the director-general of the European Space Agency (ESA), Reimar Lüst, and the President of the Commission of the European Communities (EC), Jacques Delors.

The satellite will allow Europe to have a major role in studying the world climate and the effects of pollution. But although the infrastructure of ground stations to receive data from ERS-1 is already in place, the network of potential users is still relatively underdeveloped but last month's meeting seems to have helped.

ERS-1 will also be at the heart of the World Ocean Circulation Experiment (WOCE), which will come alive, after 10 years of preparation, with the satellite's launch. Its advanced radar instrumentation will allow accurate data to be collected on sea surface temperatures, ice flows and ocean circulation, as part of an international effort to understand global

climate and natural disasters. The satellite could also be used to monitor the rate of destruction of tropical rain forests, often invisible to other remote-sensing satellites because of cloud cover.

The meeting between Delors and Lüst was aimed at soldering links between ESA and the European Community. "The European Commission is like a dream client", said Jean Arets, head of international relations at ESA. One possibility seems to be a high-level working group to encourage environmental monitoring by satellite. Arets also says that the European Community could help to finance the creation of a community of users.

The goals of ESA and the EC are reciprocal. ESA is keen to improve its coordination with the EC's new technology programmes, while the EC wishes to strengthen pan-European involvement in ESA programmes for Earth observation. It also seeks a long-term strategy to exploit microgravity techniques, and has an even more immediate need of common norms for telecommunications.

Peter Coles

## AURORAL SATELLITE

## Japan continues in an old furrow

### Tokyo

THE first satellite designed specifically for study of the particle acceleration mechanisms producing the aurora borealis (and australis) was launched successfully last week (22 February) by Japan's Institute of Space and Astronautical Science (ISAS) from the Kagoshima Space Center.

The EXOS-D satellite was carried into a polar orbit by a Mu-3S II three-stage solid-fuel rocket, independently developed under ISAS's scientific space research programme. The 300-kg satellite, given the post-launch name of 'Akebono' (Dawn), will fly into the region where charged particles from the solar wind are accelerated by the Earth's magnetic field and penetrate to the upper atmosphere, causing auroral displays. The orbit will take the satellite from a near point of 300 km from Earth out to 10,000 km.

On board Akebono are instruments to monitor magnetic and electric fields, plasma waves, low-energy particles, supra-thermal ions and thermal electrons as well as a special auroral camera

designed to take photographs in the visual and ultraviolet spectrum. Early next year, ISAS hopes to add to Akebono's view by launching sounding rockets capable of reaching a height of 350 kilometres from a base in Norway, making it possible to obtain the first simultaneous observations of the aurora from above and below.

Akebono is ISAS's 12th scientific observation satellite and the third in a series designed to look at the aurora and

Akebono: a first in aurora research.

magnetosphere, following on from Kyokko ('Northern lights') and Jikiken ('Magnetosphere'). ISAS plans to continue providing a key role for Japanese researchers in solar wind and magnetospheric research with the launch of a satellite into the Earth's magnetotail in 1992 as a part of the International Solar Terrestrial Physics programme. Alun Anderson

## TOKYO UNIVERSITY

## Close call in election fight

### Tokyo

A TOUGH election battle for the presidency of the University of Tokyo resulted in victory last week for Professor Akito Arima, one of the chief proponents of major change for Japan's leading university.

The election was so close that the university was eventually compelled to choose between two candidates by asking them to draw straws (actually a pair of bamboo sticks with concealed, differently coloured tips). It is the first time that this chance procedure has had to be used in the 112-year history of the university.

Arima (58), a theoretical nuclear physicist, will become president of the university for a four-year term beginning on 1 April. He is the first president to come from the science faculty for more than thirty years and faces a university which is divided over the plans for radical educational reform led by the science faculty.

The science faculty's plans involve fusing undergraduate and graduate schools into a new six-year school (see *Nature* 330, 597; 17 December 1987). But opponents fear it may lead to a drop in prestige for the College of General Education, whose faculty provides the first two years of education to all students and less-specialized further education in departments of Liberal Arts and Pure and Applied Sciences.

Department of Liberal Arts' Professor Nagoya Homma, who has opposed the reform plan, proved to be Arima's chief opponent.

To begin with, there were five candidates and after three rounds of voting the two top candidates both drew exactly 586 votes from the assembled professors, associate professors and lecturers of the university.

At that point, previously unused university rules specified a decision by lottery and Arima drew the winning red-tipped stick.

"Exhausting" was how one Senate member described the day-long election. But a much longer campaign lies ahead for those favouring reform. The members of the science faculty have seen top university research institutes turn into independent national facilities with excellent equipment and have seen private companies set up basic research institutes with large financial resources. Without some strengthening of the university research system, the science faculty are apprehensive that they will find themselves seen as a source of trained students rather than as leading basic researchers.

## COMPUTER VIRUSES

# No immunity for Moscow

## Moscow

COMPUTERS in the Soviet Union have been suffering from virus infections just as in the United States and Western Europe. In one of the most recent cases, at the Institute of Applied Mathematics of the Soviet Academy of Sciences, researchers found that some of their programs were disappearing for no apparent reason shortly after retrieval. Their computers had been attacked by a virus. The rogue program was quickly found and killed.

Virus infection is not new. About 20 years ago, programmers at a research institute were annoyed by the erratic behaviour of an ICL computer. The institute was on the point of sending for help from the British supplier when a young programmer admitted having written a program that fooled the operating system while remaining invisible.

With the advent of personal computers, a little too late in the Soviet Union, programmers have been confronted with a formidable job of developing anti-viral codes. The first Soviet machines to suffer from viral infections, ostensibly imported from the West, were Atari computers, followed by IBM-compatible machines.

By the time the International Computer Club was formed in Moscow last December, Soviet programmers had compiled a list of lethal files, including viruses and so-called "Trojan" programs. A user with such a list can identify the infection but cannot cure it. It takes a special anti-viral program to purge the virus.

There are now some 40 virus programs on the Soviet danger list and the number continues to grow. The computer epidemic is spreading because of the woefully inadequate software distribution system in the Soviet Union — or rather because of the lack of any such system. The result is that most Soviet programmers are engaged in entirely disorganized computer activities, seeking casual contacts with colleagues.

With no official software market, such contacts are the only way to obtain software in high demand. Among several hundred of my acquaintances who work with software best-sellers, only a handful have bought them legally.

There is no evidence that specific Soviet computer viruses have been, or are being, developed. Indeed, the best Soviet programmers are said to be working on a computer 'vaccine'. Such a program was described by the central Soviet newspapers last autumn. The idea is that the program identifies a constant part of a known virus and removes it from the host program. But such programs are not universal, as they purge only well-known viruses with 'recognition sites'.

Apart from rudimentary restriction programs, there are two anti-viral 'vaccines' in the Soviet Union. The first is a resident program monitoring a computer's 'abnormal' behaviour, which may suggest that a virus attack is under way. The other may seem more attractive to users in that it is not memory-resident and may be run after a series of operations to give a programmer a list of files which may have been modified by a virus.

Having analysed the suspicious programs the programmers can tell whether the computer system has been infected. One difficulty is that the incubation periods may be very long so that the owner of the damaged machine may discover a new infection.

Worse still, until recently there was no popular magazine for programmers, so that news about viral attacks was spread by word of mouth. The most lethal viruses, which are spread by networks, pose no danger to Soviet computers; there are almost no computer networks in the Soviet Union. Meanwhile, the need for computer virologists and for joint efforts with Western colleagues is increasingly evident.

## ANTARCTICA

# Greenpeace's claims refuted

## Paris

THE director of the research mission of the French department for Austral and Antarctic Territories (TAAF) has rejected claims by the environmental group Greenpeace that an airstrip being constructed in the French Antarctic Territory contravenes the Antarctic Treaty (see *Nature* 337, 106; 1988). Bernard Morlet says the airstrip is being built to support scientific research, and that steps are being taken to ensure that colonies of Emperor and Adélie penguins are not endangered by construction work.

Plans to build an airstrip at Dumont d'Urville date back to 1983, and are prompted by seasonal restrictions on sea access to the French base, which is surrounded by several hundred square miles of pack-ice in winter. Ships can first reach the base at mid-summer in December, and researchers arriving in January, when the base has been made habitable, have only a month to collect data if they are to avoid being icebound. An airstrip, says Morlet, will allow researchers to winter at the base and to begin work — in human and animal physiology, glaciology and climatology — once summer begins.

According to Greenpeace, the airstrip has destroyed breeding grounds for a colony of Adélie penguins and blocked the migratory path of Emperor penguins. But Morlet says that the migratory path of the Emperor penguins is variable, so that the construction may pose no problem at all, and that, in any case, they are used to climbing onto sea islands to avoid winter storms and so should be able to surmount the airstrip, which is only 5 metres above sea level.

Morlet does acknowledge that the breeding ground of the Adélie penguin, jeopardized by the landing strip, is a problem, but says that the effect of the construction project can be minimized by protecting the adult population and encouraging a change in breeding. He says that the material used for the airstrip may help to create new breeding sites. He also accuses Greenpeace of misreading the Antarctic Treaty. While its third (1983) revision forbids harmful interference with bird and seal colonies — by the use of explosives or by disturbance during their breeding periods — it also allows these activities "...to the minimum extent necessary for the establishment, supply and operation of stations".

Morlet also rejects Greenpeace's allegation that the airstrip is a foot in the door for mineral exploitation. He says that the 2,000-metre icepack beneath the French base makes it unsuitable for this purpose.

# Gorbachev's first Chernobyl visit since disaster

Associated Press

Mr Gorbachev and his wife Raisa pictured talking to workers during a visit to the Chernobyl nuclear plant last week to inspect the site of the world's worst nuclear disaster three years ago. Mr Gorbachev promised that nuclear power, while essential, was unthinkable without guarantees of complete safety — a sensitive issue in the Ukraine, which has the greatest concentration of nuclear power stations in the Soviet Union.

# Human space flight

SIR—The maxim quoted again by G. B. Field, M. J. Rees and D. N. Spergel in their otherwise excellent article (*Nature* 336, 725–726; 1988) that human space-flights “cannot be expected to yield a return commensurate with their cost if the judgement is made in purely scientific terms” is objectionable.

We need look no further than the Viking missions to Mars to see the problems of trying to automate science. Even after the expenditure of \$1,000 million (more than \$3,000 million in current dollars), nobody knows today whether or not there is life on Mars. The Viking landers failed in the single purpose for which they were built. This is not to say that they did not serve other ancillary functions, but had the landers not been constructed around elaborate biology packages, the initial reconnaissance of Mars and its system could have been accomplished for a small fraction of what was actually spent.

We forget that the Viking missions were not inexpensive relative to manned flights. Typical modern estimates for the cost of sending people to Mars (which are little changed from those during the mid-1970s) range from an unrealistic low of \$10,000 million to a more likely \$40,000 million — only 3.3 to 13.3 times the \$3,000 million cost of Viking in current dollars. Can anyone seriously argue that putting a few intelligent and flexible human beings and their equipment on the martian surface for weeks (or for months or years) will result in only thirteen times Viking’s scientific return?

Given the decisions that face the US space programme, a more relevant way to look at this issue is to consider that, even given the highest estimates for the true cost of launching a Spacelab shuttle mission (about \$500 million), the Viking expenditure would pay for no less than six Spacelab flights. Whichever way we measure it, even one Spacelab flight achieves far more science than did Viking. Does it not make sense to consolidate our position in the Earth–Moon system before we go gallivanting across the Solar System? Perhaps this could be done by building the much-maligned space station, which, in addition to laying the technological foundations for human planetary exploration, would admirably serve almost every field of space science but planetary exploration. The space station would extend all the advantages of Spacelab at a cost of only some eight times Viking.

The distinction between reconnaissance and science may seem fine, but I believe it is the natural division between what should be expected of automated spacecraft and what must wait for human

exploration. The lesson of Viking is that, for the foreseeable future, automating creative science will at best be extremely expensive and difficult, and probably impossible — whether on Earth, in orbit or far across the Solar System. This is a lesson we should consider very carefully before spending vast sums of money (\$16,000–10,000 million is the current guess) on a Mars Rover which roves less far with every study, trying to automate what a human driver could do far better for only a few times the cost.

Automated missions are tremendously valuable for some limited applications. But human missions are necessary for most sciences beyond initial reconnaissance, and planetary scientists do themselves no favours by denying that.

## The test of time

SIR—I have wasted a lot of time in my life trying to reproduce astonishing results. I know of scientists who, on any subject, publish in parallel two or three competing interpretations or theories. And a few years ago I was amazed to hear a scientist prominent in my field disclaim five articles he had recently published. It is difficult to convey the resulting scepticism about the literature to young scientists without discouraging them.

I therefore propose that when a scientist is under consideration for a new post or for promotion, his or her publications list should be checked to see whether the findings and interpretations have stood the test of time and, if not, whether they have been retracted. This complements the Harvard rule whereby only positive evidence (the four best papers) is considered. This would uncover quite a few prominent researchers whose latest sensational work always seems to obscure past errors.

## Rough justice

SIR—William McBride has some valid comments in his letter on the inquiry into his alleged fraudulent conduct (*Nature* 336, 614; 1988). On the basis of his statement that he was not allowed legal representation, nor to attend all the hearings, nor to cross-examine witnesses, he did not receive natural justice.

The transcript of the inquiry is not publicly available and analysts have only

the report to guide them. It seems that McBride should perhaps have been given the benefit of the doubt on having altered the oral dose rates because he believed he was correcting them in answer to a referee’s comment. The report makes a convincing case for finding that McBride did not use “proper scientific method” (*Report* 25; 1988) in his work. This might explain his dubious method of corrections and his incorrect statements about controls. It seems, however, that there was “deliberate falsification” (*Report* 24; 1988) about the number of experimental rabbits.

The final version of McBride’s paper, published by an Australian journal after its rejection by an overseas journal, should have been scrutinized more carefully by the referee in order to remove unsupported conclusions. Foundation 41 and its research advisory committee also performed badly, especially in their failure to investigate fully the staff allegations and to oversee remedial action.

## Apoptosis

SIR—In reply to B. Kleine (*Nature* 377, 402; 1989), J.F.R. Kerr *et al.* (*Br. J. Cancer* 26, 239–257; 1972) proposed the term “apoptosis” (suggested by Professor J. Cormack, Department of Greek, University of Aberdeen) for a process of active, programmed cell death with a number of characteristic features which clearly distinguish it from “necrosis”, passive cell death. The standard Classical Greek–English dictionary (H. G. Liddell & R. Scott, *A Greek–English Lexicon*, 6th Edn, Oxford University Press; 1869) defines ἀποπτωσις as “a falling off or away”; it is used of the falling of leaves, a clear example of programmed death. The cognate verb is, of course, the reduplicated form ἀποπίπτω; ἀποπτῶω, quoted by B. Kleine, is not known to this dictionary. A computer search of papers published since 1983 revealed fifty with “apoptosis” or “apoptotic” in the title. Had B. Kleine consulted A. H. Wylie *et al.* (*J. Pathol.* 142, 67–77; 1984), cited in our letter (*Nature* 337, 181–184; 1989), rather than his Greek–German dictionary, he would have found a clear exposition of the meaning of apoptosis.

# Pan-African ornithology divided

T. M. Crowe

A congress that once offered a forum for all African ornithologists has been dealt a crippling blow by politics. African birds and those who study them are the losers.

THE first Pan-African Ornithological Congress (PAOC) was held in Livingstone, Northern Rhodesia (now Zambia) in July 1957. The concept of the congress was the brainchild of a South African, Dr Cecily K. Mackie Niven, who was stimulated to this end chiefly by politically motivated rejections of her invitations, on behalf of the South African Ornithological Society (SAOS), to host the International Ornithological Congress in southern Africa. The first PAOC, with Niven as president, and the next two, were held under the auspices of the SAOS; the editors and many of the officials of those and its two succeeding congresses were South Africans. Dr Gerard J. Morel (chairman of the sixth congress) acknowledged that PAOC is very much a South African invention: "The credit for this unique and enviable situation [the PAOC] is largely to be attributed to our colleagues of the Southern African Ornithological Society".

In 1985, delegates at the sixth congress, held in Francistown, Botswana, voted overwhelmingly for Nairobi, Kenya, as the venue for the seventh congress in August 1988, on the assurance given by Kenyan delegates that a significant number of South Africans would be granted visas to attend. But by 1987 it had become apparent that, for political reasons, South African participation would be at best token. Indeed, for a time there was some doubt as to whether the meeting would take place at all; the Kenyan government officially approved of the congress only a few months before it was due to be held.

Fearing the consequences of a PAOC without contributions from South African ornithologists, many of the members of the PAOC *ad hoc* committee asked the local organizing committee in Nairobi to obtain an unambiguous statement of the Kenyan government's policy on the admission of South African delegates. Some also asked fellow committee members to consider an alternative venue if delegates should be denied visas. Indeed, Nairobi had been abandoned as a venue for two previous congresses on just these grounds.

The response to the first request was vague and non-committal, but it seemed that the Kenyan government would almost certainly not issue visas to South

African passport holders. The response to the second request was that the congress would be held in Nairobi "with or without South Africans". Thus, neither the *ad hoc* nor the local organizing committees considered the presence of South African ornithologists to be essential; prospective participants would have to apply individually for visas and would simply have to "take their chances".

**"One can only speculate as to how much the scientific quality of the congress could have been improved by the contributions of South African delegates, not to mention the thousands of dollars in registration fees that would have been paid by dedicated amateur South African ornithologists."**

In January 1988, those few South African ornithologists who still hoped to attend in August were instructed to provide passport details to the local organizing committee, which would then submit a block application to the Kenyan immigration department. About 15 of us provided these details. But, about three weeks before the start of the congress, I received by courier a batch of visa application forms which had to be filled out individually and returned within that week. On the same day, I received a cable notifying us that our chances of receiving visas had been "weakened by shortage of info from SA". By this time, only six of us still persisted in our determination to attend the meeting.

On the afternoon of 23 August 1988 (five days before the start of the meeting) I was told by telephone by Professor G. M. O. Maloiy, the conference chairman, that my application for a temporary visa had been approved, and that my visa would be in the hands of immigration authorities at Nairobi airport. I was also notified that a similar application for Richard K. Brooke, my colleague at the FitzPatrick Institute, had been approved, but that those of Ian A. W. Macdonald, another institute colleague, Professor Eric H. Harley (of the Department of Chemical Pathology, University of Cape Town) and of Professor Leslie G. Underhill (of the university's Mathematical Statistics Department) and his wife "... were still under consideration". Unfortunately, Brooke and Macdonald had by then cancelled their plans to attend, and Underhill

and his wife were notified by telephone on 26 August (and Macdonald subsequently by post) that their visa applications had been refused. Harley was informed of the success of his visa application on 30 August (two days after the start of the Congress).

Thus, only Harley (holder of a British passport) and myself (a US passport holder) actually attended the seventh congress, as 'official' South African delegates. Dr Richard Liversidge, also a South African resident, had travelled via London on a 'clean' British passport (and thus did not require a visa).

I arrived at Nairobi airport on the evening of 27 August to find that the Kenyan immigration authorities had no record of my visa. Fortunately Dr Hussein Isack, chairman of the local organizing committee, arrived in the nick of time with a photocopy of the visa, and kindly drove me to the hotel into which I was booked. After one evening's stay, I concluded that the hotel was not suitable: two delegates had had their rooms rifled and money and passports stolen; another delegate was brutally mugged nearby. Moreover, the hotel was frequented by aggressive prostitutes and was a costly cab ride from the congress venue, the National Museum of Kenya. Therefore on 28 August I shifted to another hotel which, although it was a mere five-minute walk from the museum, had not been offered as possible alternative accommodation by the local organizing committee.

When I registered that same afternoon I found that my delegate's badge listed the United States as my country of representation (Liversidge and Harley were listed as from the United Kingdom); the country name had been deleted from the abstracts of the two papers I was to present. My packet of congress materials also included a letter from the chairman of the *ad hoc* committee threatening to disrupt the presentation of my papers and to prevent me from attending future congresses if I did not submit manuscripts for the congress proceedings during, or shortly after, the meeting. (I had questioned the hard-and-fast rule in the proposed PAOC constitution that no oral paper could be presented if a complete manuscript was not also delivered.)

Although the seventh congress was

well-attended (more than 100 papers and more than 200 delegates from 19 African and 14 non-African countries), the organization of the programme, the quality of the papers and their relevance to African conservation biology left much to be desired. The original intention had been to have sessions or mini-symposia with themes (seasonality, birds as biological indicators, nest parasitism, pest birds, biogeography and systematics, and so on), many of these were decimated by the enforced withdrawal or exclusion of South African ornithologists. For example, my session on systematics and biogeography had the heart ripped out of it with the absence of Dr Alan C. Kemp (Transvaal Museum), Tony Harris (Transvaal Museum) and Dr W. Stewart Grant (University of the Witwatersrand). I read brief summaries of Kemp's and Grant's papers, but papers delivered *in absentia* have little impact and do not appear in the congress proceedings.

Similarly, the session on birds as indicators of environmental change, which had been organized by Ian Macdonald, was, without him, a ghost of what it could have been. One can only speculate as to how much the scientific quality of the congress could have been improved by the contributions of South African delegates, not to mention the thousands of dollars in registration fees that would have been paid by dedicated amateur South African ornithologists.

On a more positive note, about a quarter of the oral papers were presented by indigenous Africans. But with certain noteworthy exceptions, their presentations were either dry or emotive descriptive accounts or 'how-to-kill-quelea'-type recipes. Few of these papers were based on statistically sound and analysed quantitative information. These deficiencies were certainly not due to the presenters' difficulty with the English language or a lack of dedication, enthusiasm or intellectual ability, but rather can be attributed to poor training in fundamental biological concepts and analytical skills.

### Poor science

Perhaps the most disturbing aspect of the meeting was the poor scientific quality of the conservation papers. Clearly, the main threats to African birds relate to the fragmentation of their habitats (because of man's land-use practices) and concomitant reduction in species' populations. It is simply not good enough to preserve a patch of the preferred habitat of a species if that is too small and isolated to maintain a minimum viable population. Only one paper, by W.D. Newmark, and delegates at a workshop on forest ecosystems convened by Dr Simon Stuart, specifically addressed these issues. At a similar workshop on savannah ecosystems, the convenor was apparently unaware of

the importance of studies of minimum viable population size.

Papers presented during the 'conservation' day devoted to the International Council for Bird Preservation were mainly conservation status-type papers and accounts of educational programmes. There was little or no quantitative biogeography, ecology, genetics or socio-economics. Our job as ornithologists is to provide conservationist organizations' negotiators with the necessary scientific ammunition to sway decision-makers in governments. It is not sufficient merely to make resolutions that this or that chunk of habitat needs to be preserved, but rather to make explicit, scientifically sound predictions about the consequences of its preservation or destruction.

The key clauses in the PAOC constitution that will effectively prevent South African participation in the two remaining congresses this century are the aim to rotate the venues among the four regions of Africa (east, west, central and southern) and the limitation of a single country's membership on the PAOC committee, the ruling body, to a maximum of 3 out of the 20 members. The selection of venues means that the next two congresses will almost certainly be held in central and west Africa. The apportionment of committee members on a strictly regional basis takes no account of geographical variation in the abundance or quality of African ornithologists. Thus, in theory, there could be no South African representation on the committee, but west Africa, which appears now to have no trained resident scientists at PhD level working full-time on birds, will have four members on the committee. When I brought up the issue of the importance of free access to all in choosing a PAOC venue, only one committee member felt that this should even be considered.

One positive development was nevertheless that the committee agreed to consider being indirectly affiliated with the International Council of Scientific Unions. If PAOC adopts the council's code, no venue could be chosen which would exclude delegates on political grounds. But this would not help amateur South African ornithologists, most of whom would still be unable to attend as they do not present papers, the rules applying only to delegates who do present them. This is a particularly tragic blow to African ornithology as nearly half of the delegates attending the first six PAOCs were South African, most of them being dedicated amateurs.

The primary criterion which influenced the choice of the venue for the next PAOC was that it must be in a French-speaking African country. Other factors, such as ease of access (financial and political), excellence of site and excursions or the relevance of birds to local conservation,

were of secondary importance. On this basis Kigali, Rwanda, was chosen as the venue of the eighth PAOC to be held in 1992, with Ghana as a prospective venue for 1996.

### Bitter pill

The PAOC created by Niven is now extinct, and has been replaced by a very different sort of animal. I have reservations about the 'fitness' of this new creature, but will support it as long as there is a reasonable chance of it promoting African ornithology. My message to my South African colleagues is perhaps a bitter pill. As African ornithologists, however, we must endeavour to maintain our tenuous ties with our colleagues to the north. These people need and want our collaboration and we would be remiss if we allowed political differences between governments to sever our ties with them. The virulent anti-South African elements in the PAOC committee are but a comparatively small section of the tail of this animal, powerful enough at the moment to wag the dog, but we have every reason to hope that that power will wane.

At the same time, although the passing of the SAOS-style PAOC is to be lamented, we must continue to promote South African ornithology by sending our best ornithologists, especially young graduates, to discuss their research at international conferences. We must also promote ornithology locally by hosting international conferences in South Africa.

Finally, for too long ornithology in South Africa has been effectively a reserved white profession. This country and its wildlife belong to black as well as white South Africans. As a result of setting and maintaining high standards in our bird research, we have made it very difficult for educationally deprived black people to establish themselves as ornithologists. I believe that we (the SAOS and the FitzPatrick Institute) should do much more to publicize our activities and create incentives to promote the development of black ornithologists, and that we should take active steps to interest black South Africans in conservation biology and ornithology. The University of Cape Town (as well as other open universities) has active academic support programmes which are helping to redress the educational imbalance created by apartheid. □

*T.M. Crowe is at the FitzPatrick Institute, University of Cape Town, Rondebosch 7700, South Africa.*

**ACKNOWLEDGEMENTS.** I thank the Bremner Travel Grants Committee and FitzPatrick Institute (University of Cape Town) and the Foundation for Research Development of the Council for Scientific and Industrial Research for financial and other support that made my trip possible and successful. I thank Professor G.M.O. Maloiy and Dr Hussein Isack for their help with my obtaining a visitor's visa for Kenya and their friendship and hospitality during my stay. This article is a personal assessment of the seventh PAOC and does not necessarily reflect the views of my colleagues or the SAOS council.

## With our Beta counters you can use all types of vials – or no vials at all

The new SYSTEM 1400™ LSC allows you to count directly from microfuge and Eppendorf tubes as easily as from any commonly used LSC vial type. For better results and smooth working routines, you choose your vial to suit your application.

- Microfuge and Eppendorf tubes go directly into the counter.
- 336 to 1248 sample capacity.
- New approach to DPM calculation, saves work and enhances results.
- Results preformatting to meet every user's precise needs.

The 1205 Betaplate™ LSC allows you to count filtered or spotted sample entirely without vials. A new procedure gives you big savings in time and money, at the same time improving the quality of your results.

- For labelled cell studies, cytotoxicity, receptor binding, enzyme assays, etc.
- No vials needed – the filtermat goes directly into the counter
- 1920 sample capacity.
- Vast savings in time and consumables.
- Eases waste disposal.

### Confirming technology leadership in liquid scintillation counting

SYSTEM 1400™ is the new generation multipurpose LSC. It is packed with innovative features to improve results and make work more rewarding.

The 1205 Betaplate™ counts filtermats directly. It saves time and labour, and leads to big savings in consumables and waste disposal.

***So you lost a week's work with a popping lid.***

**Next time use Multi-Cap-Locks™ and Multi-MAX Seal Tubes™.**

In a comparison with other micro centrifuge tubes, Multi-MAX Seal Tubes™ more effectively prevent evaporation.

Multi-MAX Seal Tubes™ utilize an innovative design with two applications in mind:

- (1) Use under extreme conditions where sample loss can be a problem (i.e. boiling.)
- (2) Long-term storage of liquid samples.

When used in conjunction with the Multi-Cap-Lock™, the O-ring in the lid of the tube forms an air-tight seal which remains intact even when the tubes are taken directly from liquid nitrogen to boiling water. Boiling for periods of up to 30 minutes has been shown to result in no loss of samples.

Multi-MAX Seal Tubes™ provide a seal as effective as screw-top tubes, but with the convenience of standard microfuge tubes!

human fetus (H.E. Stain)  
S Plan FL1X NFK2.5X

## ***Olympus autofocus photomicrography takes the error out of focusing***

What the naked eye perceives as sharp and clear often translates into a blurred image on film or paper.

Now Olympus brings you the Vanox-S—the world's first autofocus photomicroscope system—designed to eliminate focusing error in low magnification photomicrography (objectives from 1X to 10X), and ensure needle-sharp imagery throughout the entire magnification range. All you have to do is push the AF button.

And the Vanox-S also enables the use of two 35mm cameras and a large-format camera, incorporated into the body, together with automatic exposure and four photo eyepieces. Light intensity is adjusted with neutral density filters, maintaining color temperature consistency.

The new Vanox-S research photomicroscope system lets you reproduce the actual image you see accurately and with high quality. More easily and consistently than ever before.

**POSTER SESSIONS OPEN TO ALL PARTICIPANTS: Deadline for abstracts April 15, 1989**

International Exhibition - the publishers of NATURE will be organising an associated international exhibition.

### Satellite meetings:

- Utrecht August 18-20** "Early amphibian development", organiser A.J. Durston. Participants include: Carrasco, A.E. (Houston), Dawid, I. (Bethesda), Duprat, A.M. (Toulouse), Dworkin, M. (Vienna), Goodwin, B.C. (Milton Keynes), Gurdon, J. (Cambridge), Johnson, K. (Washington), Meinhardt, H. (Tübingen), Mohun, T. (London), Nieuwkoop, P.D. (Utrecht), Smith, J. (London), Tiedemann, H. (Berlin).
- Groningen August 17-19** "Pathobiology of human germ cell tumors", organisers I. Damjanov, J.W. Oosterhuis, H. Walt. Invited speakers: Andrews, P.W. (Philadelphia), Castedo, S.M.M.J. (Porto), Damjanov, I. (Philadelphia), Engström, W. (Stockholm), Graham, C.F. (Oxford), Pera, M.F. (Oxford), Sikora, K. (London), Skakkebeak, N.E. (Copenhagen).
- Utrecht August 25** "Microgravity as a tool in developmental biology", organiser: G.A. Ubbels.

### Grants

The organising committee has a limited amount of grant money available for young scientists, under the age of 35, wishing to attend this meeting. Applications including curriculum vitae and an abstract to be sent to: ISDB Congress, c/o Hubrecht Laboratory, Uppsalalaan 8, 3584 CT Utrecht, The Netherlands. Tel. 31.30.510211, Fax 31.30.516464.

Complete and return the form below to receive the final announcement.

Return to:

# How to say sorry graciously

Mistakes will happen, so that retractions will continue to be necessary. Two physicists have now produced a model of how the task should be tackled.

RETRACTION has become a loaded word, which journals and their contributors alike abhor. As things are now in the United States, there is even a danger that the mere appearance of a retraction will be regarded by a congressional committee or by a self-appointed watchdog as a signal for an inquiry into what has been going on. That is one reason why there should be some rejoicing that it is still possible to publish a full, even a fulsome retraction without bringing down the house on one's head. What has happened is that two physicists at the University of Maryland at College Park (almost in suburban Washington) have retracted the conclusions of an article that appeared last year in no less a journal than *Physical Review Letters* (59, 2507; 1988), but they have done so in such an open fashion that even their sternest critics will be disarmed.

The tenor of the retraction can best be judged from the sentence towards the end in which the authors, O.W. Greenberg and R.N. Mohapatra, say: "We are grateful to Rudolf Haag for warning us of the error of our ways". They then go on to thank another colleague for drawing their attention to an article in the Soviet literature which, if read in time, would also have warned them off. They acknowledge in their retraction (*Phys. Rev. Lett.* 62, 712; 1989) that many people have already embarked on experiments to test their earlier theory. But the best guess seems to be that those who have started down that road will continue, if only because the issue is in itself intrinsically interesting.

The question is whether there can be violations of Pauli's exclusion principle which, applied to electrons, forbids the simultaneous presence of two particles in the same state. An entirely equivalent way of putting this restriction is to say that the complete wavefunction of a system of several electrons (or other particles of the family called fermions) must be anti-symmetric with respect to the exchange of any two of them.

But that formulation has the advantage of suggesting that the wavefunction of a system of several bosons must be symmetric with respect to the exchange of random pairs of particles. The practical consequences are of course considerable. Fermions obey Fermi statistics and bosons (such as photons) obey Bose-Einstein statistics, which explains why the free electrons in a metallic conductor make

only a negligible contribution to its specific heat.

There is a third formulation of Pauli's principle which field theorists find more useful. A particle field, say some arbitrary distribution of radiation (photons), can be conveniently represented with reference to the dynamically possible states of a single photon in the available space. The simplest way of cataloguing the states is by means of the multiply infinite set of states defined by the standing waves which can exist within whatever space is accessible, each of which corresponds to a simple harmonic oscillator whose frequency corresponds to that of the radiation (when the bosons are photons).

Starting from that point and the principle that, in quantum mechanics, observable quantities are operators, the field theorists have fashioned a formalism in which the actual state of a system, which should be a specification of the numbers of particles in each of the possible oscillatory states, can be built up from the interaction of elementary operators, one set for each possible state, which have the effect either of creating or getting rid of a particle from that state. The creation and annihilation operators are the life-blood of field theory.

They are also the simplest means by which departures from Pauli's principle can be handled. For it is clear that the creation operators for fermion and boson fields must have very different properties. Two fermions cannot be in the same state, which means that although the effect of a creation operator on an empty fermion state is to fill it with a single particle, Pauli's principle implies that a second operation on the same state must be a nonsense. But with bosons, the creation operators must plainly behave differently, because there can be many particles in the same state. The algebra that arises by forming the products of several of these operators is simple but intriguing.

Greenberg and Mohapatra's original goal was to study small departures from Pauli's principle. Large departures would not have been surprising in the sense that there is a theory (going back to the 1950s) allowing for particles (which apparently do not exist) with properties intermediate between bosons and fermions, and called parafermions and parabosons. And, of course, they suggested experiments to tell how big the

departures are, or at least to define bounds for them.

Designing experiments is not as difficult as it may seem. If, for example, there is a chance that a single fermion state may occasionally hold two particles, it should be possible to discover that X-rays emerge from conductors carrying electric current, as electrons are occasionally captured into inner energy levels which temporarily violate Pauli's principle. Greenberg and Mohapatra report how some colleagues have completed such an experiment at Fermilab without finding anything untoward.

So where did Greenberg and Mohapatra go astray? Their starting point had been a modification of the algebra of the creation and annihilation operators, which they assumed to be feasible because it had been tried before. What they did not know was that a Soviet researcher, A.B. Govorkov from the international centre at Dubna, had shown as early as 1983 that the mathematical properties of the creation and annihilation operators forbid modifications other than those leading to the uninteresting states of parafermions and parabosons.

One virtue of this retraction is that the reasons why the argument went awry are fully explained, at least in language that those working in the field will readily understand. Another is the good humour of the piece, typified by the acknowledgement of Rudolf Haag "for having shown us the error of our ways". Yet another is the way that those who have helped to put the authors back on the straight and narrow path of rectitude are thanked for their help. And, finally, there are the grant-making agencies: support from the National Science Foundation is acknowledged in exactly the same terms in the two papers.

More than all this, the authors go on to give general reasons why their search for a basis on which Pauli's principle may be violated was a wild-goose chase from the start. The formalisms that give parabosons and parafermions correspond to the orthogonal and unitary symmetry groups of particular integral dimensions, but nobody has yet found a way in which these groups can be generalized into non-integral dimensionality. It seems rather hard on the authors to suggest that their retraction should be taken as a model in this rare genre, but that is what it is.

John Maddox

# Initiation of recombination

J.R.S. Fincham and P. Oliver

RECOMBINATION within genes is generally by conversion — that is, by unilateral transfer of information from one allele to the other. It can be, and often is, accompanied by nearby crossing over, but it is most often the conversion rather than any correlated crossover that is responsible for the recombination within the gene. Much of what is known about this process comes from yeast and other fungi, where conversion shows up as non-mendelian ratios — 3:1 or 1:3 instead of 2:2 — in meiotic tetrads segregating with respect to single mutational differences. The complexity of the alternative models for the mechanism of recombination, although plausible, has hitherto detracted from their testability. Now that Szostak and colleagues have broken into meiotic recombination at the molecular level, as they report in two papers on pages 35 and 87 of this issue<sup>1,2</sup>, we may hope for the emergence of a better verified picture, though no doubt still a complex one.

One of the observations on meiotic conversion that must be explained by hypotheses is that mutational sites often show a gradient of conversion frequency from one end of the gene to the other. This phenomenon, termed conversion polarity, has been taken to suggest that there is a conversion initiation site at one end of the gene and that the probability of a given mutational difference (genetic marker) being involved in conversion decreases with increasing distance from that site.

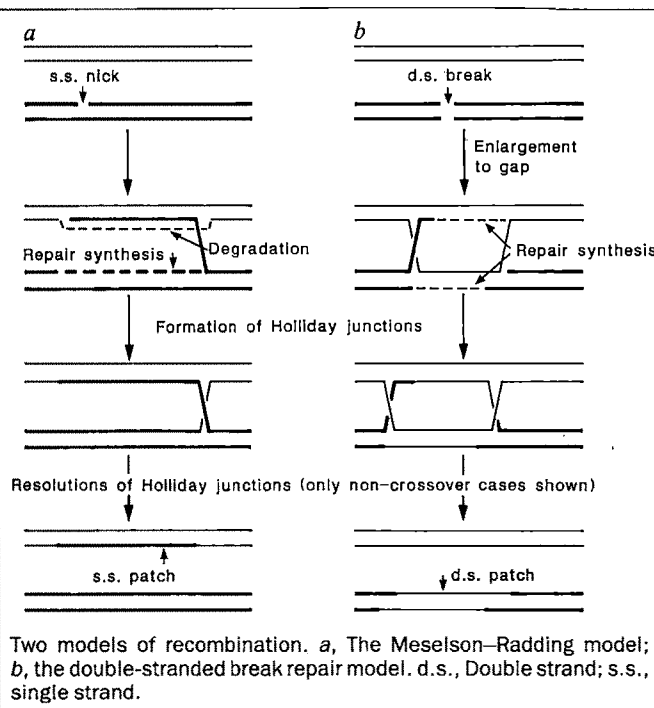

There are two radically different general hypotheses or models of recombination (see figure). Both involve the formation of single-strand exchanges (Holliday junctions) between homologous double-stranded DNA sequences, but they differ in the postulated origin of these junctions. Meselson and Radding's model<sup>3</sup>, which is an adaptation of Holliday's original concept, postulates the assimilation of single-stranded DNA from one duplex into the homologue, displacing the corresponding resident strand starting at a more-or-less fixed point. It is supposed that the displaced strand is destroyed and the single-strand gap in the donor duplex filled by new synthesis. If there is a mutational difference leading to non-complementarity between the invading strand and its new partner, mis-match correction may either restore the recipient to its original sequence or convert it to the sequence of the donor. If no correction

takes place, just one of the two products of the next round of DNA replication will show the conversion (post-meiotic segregation). In this model, the probability of conversion depends on the probability that the genetic marker is included within hybrid DNA which is pictured as extending for a variable distance from the initiation site; hence the closer the marker to the initiation site, the greater the chance of its being involved in conversion. In the original model<sup>4</sup>, the process of single-strand transfer was supposed to be initiated by single-strand nicking in the donor DNA, but another possibility is that it

be the precursor of at least those conversion events associated with post-meiotic segregation, and is now generally accepted as likely to be the immediate precursor of many conversion events. But the Szostak model can also accommodate heteroduplex at the margins of double-strand repair patches. Both invoke a site of preferential cleavage for the initiation of recombination, with the implication that deletion of this site should reduce recombination frequency. But whereas the double-strand gapped duplex in the double-stranded break repair model is necessarily the recipient of genetic information, the single-strand-nicked duplex in the original Meselson–Radding model is the donor. However, in Radding's alternative version of the Meselson–Radding model<sup>4</sup>, it is the single-strand gap in the recipient duplex that initiates conversion.

Both models suggest that the events leading to conversion are also responsible for crossing over, through one kind of resolution of the Holliday junctions. Thus both would give the putative initiation sites an essential role in all recombination, including exchanges of chromosome segments as well as conversion.

In the first of the two papers from Szostak's laboratory in this issue<sup>1</sup>, Nicolas *et al.* present the first evidence at the molecular level concerning the mechanism of conversion polarity. The object of study is the yeast *Saccharomyces cerevisiae* ARG4 gene, in which conversion polarity was demonstrated many years ago by classical genetic methods<sup>6</sup>. First, Nicolas *et al.* introduced various kinds of mutations *in vitro* into defined positions in the cloned gene and, through the now

might be provoked by the appearance of a single-strand gap in the recipient.

The alternative hypothesis of Szostak *et al.*<sup>5</sup>, termed double-stranded break repair, postulates that recombination is initiated by a double-stranded cut that may become a gap by erosion of the cut ends. According to this model, which is strongly supported by experiments on the recombinational behaviour of yeast plasmids containing a double-stranded gap, conversion is the result of repair of the gap by copying from both strands of the undamaged homologue. On this view, polarity could result, at least in part, from variable extents of gapping, with the chance of a marker being included in the gap decreasing with increasing distance from the site of gap initiation.

The two models are not very dissimilar in several of their predictions. The Meselson–Radding model most obviously provides for the heteroduplex which must

routine tricks of yeast molecular genetics, substituted these artificial mutations into the yeast genome. Genetic analysis of crosses between each of these defined mutants and the wild type show a gradient of conversion frequency essentially identical to that previously demonstrated for *arg4* mutations *in vivo*.

In the crucial second phase of their investigation, Nicolas *et al.* made deletions of various segments in and adjacent to the upstream (high-conversion) end of the gene, and tested them for their effects on conversion frequencies of sites at different distances downstream. Deletions covering the region from 30 to 300 bases upstream of the transcription initiation site, when they are present in both parents of a cross, abolish the polarity and reduce the conversion frequency at all sites — not to zero but to a level similar to that which is normally found at the low end of the conversion gradient.

The authors suppose that the main *ARG4* recombination initiation site lies in the -300 to -30 segment, which also happens to include the *ARG4* promoter. When they brought a marker normally at the low end of the conversion gradient close to the promoter by deleting most of the intervening sequence, its conversion frequency was increased to the level characteristic of the high end of the gradient. They attribute the residual conversion activity following the deletion of the putative conversion initiation region to recombination initiated at other, probably more distant sites. When the putative initiation region is deleted in one parent but not in the other, it is the non-deleted partner that is the preferred recipient of information in conversion; there is a large excess of 3:1 over 1:3 ratios of deleted to wild-type products (conversion disparity).

This is, of course, what the double-stranded break repair model would predict. In a substantial proportion of such 3:1 tetrads, a marker several hundred base pairs downstream of the deletion is included in the conversion event, as if the gap extended for at least that distance from the initiation site. Deletions not covering the promoter/initiation region show no conversion disparity, or a disparity not held to be statistically significant (a somewhat questionable conclusion in one case).

In the second paper in this issue from Szostak's group, Sun *et al.*<sup>2</sup> report on the fate, in a diploid culture synchronized in meiosis, of replicating plasmids carrying cloned chromosomal DNA, including the *ARG4* gene, with the putative initiation region either present or deleted. Restriction fragment analysis shows that, when this region is present, three double-strand breaks appear at different sites in the cloned DNA; these are all in, or close to, known promoter regions and one of them (site 2) is in a position consistent with that of the putative *ARG4* recombination initiation site. Each of the breaks affects only a small proportion of the plasmid molecules, perhaps not too different from the observed frequency of gene conversion in *ARG4*. They appear early in meiosis and disappear as meiosis is completed. Plasmids with the putative *ARG4* initiation region deleted are still cut at sites 1 and 3, but not at site 2. These observations provide strong evidence that the recombination initiation site is readily breakable in meiosis and suggests

that a double-strand cut may be the initiating event.

Another observation of considerable interest<sup>2</sup> is that the fragments are substantially shortened by single-strand exonuclease, implying that they have long single-stranded tails. Assuming that these tails are not artefacts of cell disruption, this observation suggests that the gap-

repair process involves the formation of longer tracts of heteroduplex than had previously seemed likely. This would give the double-stranded break repair model still more versatility in explaining the genetic phenomena. □

J.R.S. Fincham and P. Oliver are in the Department of Genetics, University of Cambridge, Downing Street, Cambridge CB2 3EH, UK.

## METEOROLOGY

# Cold waters and hot summers

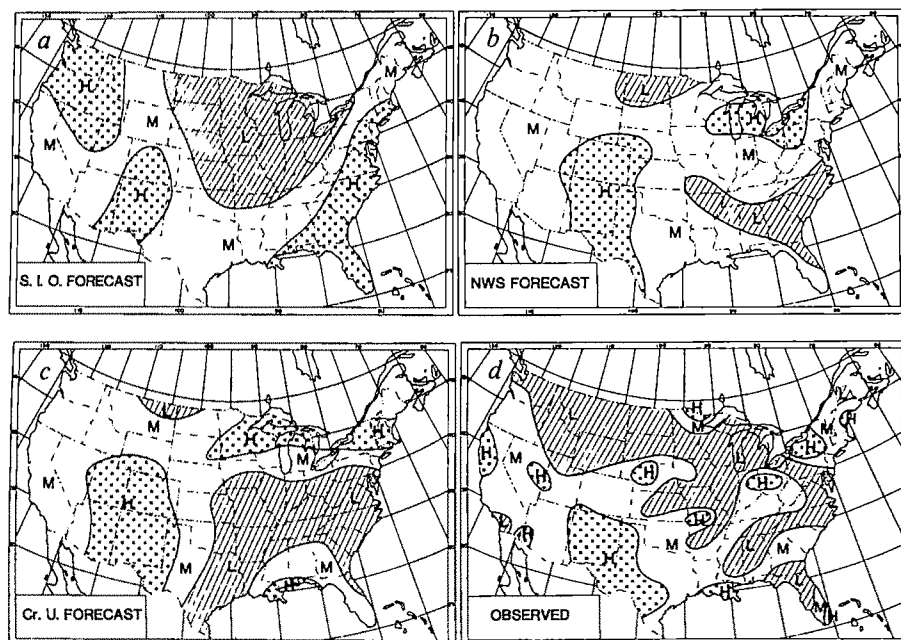

Jerome Namias

THE great US drought of the summer of 1988 was linked to sea-surface-temperature changes, according to Palmer and Branković on page 54 of this issue<sup>1</sup>. Their work extends the recent studies by Trenberth *et al.*<sup>2</sup> who attributed the drought mainly to the arrival of exceptionally cold water in the tropical Pacific (La Niña) in the aftermath of the warm El Niño event of 1987. The novelty of these two contributions is not that abnormal sea-surface-temperature patterns are necessary links in the climate system during the droughts in the United States, but that a surface-temperature anomaly in a specific region is the main culprit.

Empirical studies of many great droughts of this century have demonstrated that summer drought over the United States is part of a larger picture in which three upper-level high-pressure cells — over the North Pacific, the North Atlantic and the United States — interact in a mutually supporting fashion. The term teleconnections has been applied to

such interactions — a phenomenon first explored by Sir Gilbert Walker<sup>3</sup>.

Palmer and Branković<sup>1</sup>, like Trenberth *et al.*<sup>2</sup>, have used state-of-the-art numerical models to make their case. Trenberth *et al.* showed that the three-cell flow pattern at a height corresponding to 300 millibars (in the upper troposphere) is reasonably well simulated if the model is initialized with the abnormally cold sea surface temperature that existed in the tropical North Pacific during the drought. Palmer and Branković compare model global simulations and 30-day weather predictions made starting with the conditions in May 1987 (when no comparable drought existed) with those initialized with the conditions in May 1988. Both papers indicate that sea-surface-temperature boundary conditions were necessary links in the establishment of drought in North America and conclude that the primary cause lay in the tropics where La Niña occurred in 1988. (La Niña is a period characterized by the presence of

Forecasts of (a-c) precipitation classes for summer 1988; a, by myself and D. Cayan; b, the Long Range Prediction Group of the US National Weather Service; and c, Douglas of Creighton University. d, The observed patterns. Classes are terciles computed from 30 summers. L, light; M, moderate; and H, heavy. The models predicted the drought, but not its severity.

5. Szostak, J.W. *et al.* *Cell* **33**, 26-35 (1983).
6. Fogel, E. *et al.* in *The Molecular Biology of the Yeast Saccharomyces* (eds Strathern, J. *et al.*) 289-339 (Cold Spring Harbor, New York, 1981).

anomalously cold surface water in the North Pacific Ocean, and frequently follows El Niño, a period of anomalously warm waters. The cause of these events is unknown, but they have been associated with many types of climate change.)

I believe the conclusion these groups draw is too strong, and argue elsewhere<sup>1</sup> that La Niña is only one of several factors, and by no means the strongest one, associated with the drought through the three-cell structure. Indeed, Trenberth *et al.* and Palmer and Branković acknowledge that this localization of the primary cause is far from conclusively demonstrated by the model results, even though the effect of hemisphere-wide sea-surface-temperature anomalies is strongly suggested. The anomaly patterns are closely related to atmospheric flow patterns, and the cold La Niña water and the warm pool of water just to its north could be either causes of or responses to remote events. Also, Palmer and Branković's data are at best suggestive: there is a disturbing spatial offset between the differences in 300-millibar height patterns and temperature and precipitation patterns over North America and adjacent areas predicted, and those observed.

As both sets of authors point out, the drought of 1988 and its causes could be unique. Many major North American droughts of this century have not been associated with La-Niña-type conditions, although the three-cell pattern has occurred. Dry soil in spring in the mid-west, which generates a high-pressure cell<sup>5</sup>, is conducive to drought (as Trenberth *et al.* acknowledge) and was a factor in 1988. And warm water in either the North Atlantic or North Pacific would also generate high-pressure, anticyclonic cells. It is possible that in the present case, the La Niña event was so strong that it simply eclipsed the other air-sea-land interactions. Thus as is found in other similar studies, cause and effect are hard to distinguish.

The influence of the tropics on atmospheric general circulation, as highlighted by these new studies, is clearly important. Although the drought last year was foreseen in empirical models its severity was underestimated (see figure). Future predictions could benefit from our improved understanding. One thing, however, is absolutely clear: the drought was a consequence of normal atmospheric variability, and has no connection whatever with the greenhouse effect. □

## Detecting density dependence in imaginary worlds

Robert M. May

CHAOS — in the form of simple and fully deterministic systems that exhibit very complicated and effectively unpredictable dynamics — is much in the news, partly, I think, as a result of Gleick's popular book<sup>1</sup>. Although the practical implications of deterministic chaos were first recognized by Lorenz<sup>2</sup> in a meteorological context and by Yorke, Oster, myself and others<sup>3–5</sup> in dynamics of animal populations, most of the recent excitement centres on applications to chemical, physical, electrical and physiological systems, where cascades of period doubling and other related phenomena can be observed in a precise and satisfying way. Among the many reasons for the shift in emphasis is the fact that the magnitudes of real populations of plants and animals are rarely governed by simple nonlinear equations that could provide crisp illustrations of chaotic behaviour. Rather, such populations are typically affected by interactions with many others and by unpredictable environmental fluctuations. The result is a confused picture, with no general agreement about the implications of chaotic phenomena for biological populations<sup>6,7</sup>. A recent paper by Mountford<sup>8</sup> sheds some light on these questions.

One of the uncertainties concerns the extent to which strong nonlinearities and the possibility of chaotic dynamics in natural populations might, in certain circumstances, invalidate conventional methods of analysing data. In the past, the implicit assumption has been that density-dependent effects would regulate a population to some constant value, or at worst to a stable cycle, were it not for unpredictable fluctuations in environmental and demographic parameters. The task thus seemed to be one of extracting a regulatory 'signal' from obscuring 'noise', and conventional techniques (such as *k*-factor analysis, which essentially seeks patterns in the relation between population densities in successive generations) are implicitly based on this. But what if the observed fluctuations in population densities derived partly from real 'noise' and partly from deterministic chaos (apparently random fluctuations produced by a simple density-dependent relation)?

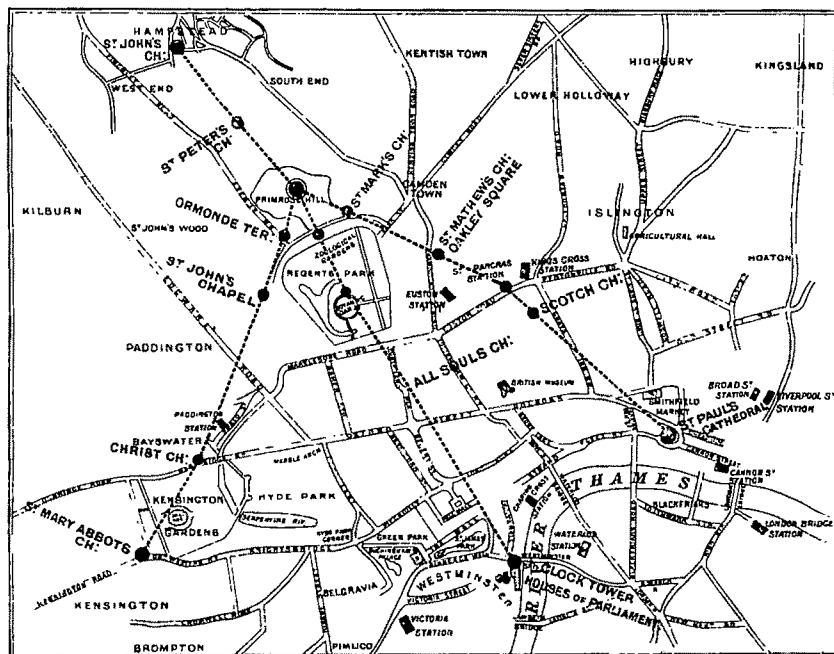

Hassell<sup>9</sup> has attacked this question by examining the extent to which standard techniques of data analysis can uncover the rules obeyed by imaginary populations of his own creation. This general idea is useful in other areas of ecology, for example Colwell and Winkler's exploration of the extent to which prevailing methods could uncover the biogeographical rules

whereby their computer program colonized simulated archipelagos of islands with simulated species<sup>10,11</sup>. Hassell's 'pseudo-data' were generated by a program that embodied ideas about how some insect populations may behave: in each generation adults were distributed (according to a statistical recipe) among many different patches; in each patch, the adults laid eggs; larvae then emerged, and their probability of survival to adulthood depended, in a specified way, on the density in that patch; in this way, the next generation of adults was produced.

Hassell also superimposed various kinds of stochastic fluctuations (in the number of eggs laid by individual adults, for example, or in the patterns of distribution of adults among patches) on his system. If the density-dependent effects acting on larval survival were sufficiently severe, then Hassell's pseudo-data showed irregular fluctuations that were a mixture of the genuine noise he introduced and oscillatory or chaotic fluctuations produced by density-dependent effects. Even when density dependence regulated the population to a constant value in the absence of environmental noise, the stochasticities introduced by Hassell could lead to fluctuations in parameters influencing the severity of density-dependent effects, which in turn could cause the sporadic manifestation of chaotic dynamics.

Applying *k*-factor analysis to these pseudo-data, Hassell could sometimes detect the underlying density-dependent mechanisms that ultimately regulated his populations, and sometimes could not. That is, in this system where the overall density in any one generation depended on a patchy distribution, where density-dependent effects acted differently at different densities in different patches, and where superimposed noise of various kinds made chaos possible in some patches, the regulatory 'signals' were masked by some kinds of noise, but not by others. Hassell *et al.*<sup>12</sup> have now applied these insights to an analysis of about 20 years of data on the abundance of whitefly populations on leaves on viburnum bushes at the Imperial College Field Station at Silwood Park, and seem to have detected density-dependent effects that were not revealed by conventional analysis of the data for overall average whitefly populations in successive generations. But these preliminary studies leave open many questions about which kinds of environmental noise do and do not mask density-dependent signals in Hassell's simulations,

## 100 years ago THE DARKNESS OF LONDON AIR

THE constitution of London fogs has been carefully gone into by several well-known men of science; and the results obtained are of very great interest, as they prove, amongst other things, that during the winter London air has an unusually large amount of carbonic acid in it. Various observations were taken in London during the winter of 1887-88. During the five months selected, Christ Church, Lancaster Gate, and St. Mary Abbot's Church, Kensington, on the south-west line; the Clock Tower, Houses of Parliament, on the south line, and the Scotch Church, Regent's Square; and St. Paul's Cathedral, on the south-east line, were *never once* seen. When it is known that on any fine day during the late spring, summer, and early autumn, you can see right across London, on any one of the selected lines, it will be easy to realize how thick the air over London is during the winter. From *Nature* 39, 442; 7 March 1889.

much less in the real world.

In his new paper<sup>8</sup>, Mountford has extended this discussion. Hassell assumed that the competitive effects determining larval survival are 'scramble': when resources are abundant, all do well, and when resources are sparse, all do badly. The result can be a highly nonlinear, 'boom-and-bust' relation, which can fairly easily produce oscillatory or chaotic dynamics. Mountford, on the other hand, bases all his simulations on density-dependent relations corresponding to 'contest' competition, which assumes resources are distributed in a hierarchical fashion, so that a few individuals do well even in hard times. These smooth relations chosen by Mountford to characterize larval competition can never generate oscillatory, much less chaotic, dynamics. With his pseudo-data generated in this way, Mountford finds that conventional methods can easily detect the density-dependent effects, with spatial heterogeneity and environmental noise presenting no difficulties.

The problems discovered by Hassell seem to me to depend largely on the interplay between what might be called 'density-dependent noise' (generated by non-linear relations that, in some patches in a fluctuating environment, can be severe enough to produce chaos) and 'density-

independent noise' (generated directly by environmental stochasticity), in a patchy world<sup>13</sup>. So I am not surprised that these problems do not arise in systems such as Mountford's, where the nonlinearities are too weak to produce oscillations or chaos. It is perhaps unfortunate that Mountford does not mention this qualitative difference between his chosen density-dependent functions and the boom-and-bust ones of Hassell; the differences between Hassell's and Mountford's simulations seem puzzling if this underlying difference is not appreciated.

This being said, Mountford's study is interesting in several ways. First, it is useful to have an explicit indication that patchiness and stochastic effects, by themselves, are insufficient to upset traditional methods of data analysis. Severe nonlinearities in density-dependent effects thus seem to be an essential ingredient in such problems as may exist. Second, Mountford shows that (in the absence of strong nonlinearities) spatial heterogeneity can actually enhance our ability to detect density dependence: "if there are a number of sets of population density series all with the same mean and the same variability but with differing degrees of spatial heterogeneity, then the detection of density dependence improves with increasing spatial heterogeneity". Third,

the pronounced differences between Hassell's studies (based on 'scramble' competition, with its potential for strong nonlinearities and chaotic dynamics) and Mountford's (based on 'contest' competition) highlight the often-neglected way in which the behaviour of individuals influences the dynamics of populations. Indeed, Lomnicki's recent book<sup>14</sup> is devoted to showing explicitly how some kinds of foraging (or other) behaviour result in 'scrambling' competitive relations and thus in highly volatile dynamics for the population, while different kinds of individual behaviour result in 'contest' competition and thus in tame dynamics. The comparison between Hassell's and Mountford's papers provides another perspective on Lomnicki's basic theme.

There seems to me to be much scope for further studies of ways in which spatial heterogeneity, environmental unpredictability, and nonlinear interactions within and between populations can swirl together to confound empirical studies aimed at understanding what prevents the long-term average density of a population from increasing indefinitely (or decreasing to zero in a time short compared with average extinction times). Using computers to generate pseudo-data for imaginary worlds whose rules are known, and then testing conventional methods of data analysis for their efficiency in revealing these known rules, seems to me to be a useful approach. We must all, of course, join Mountford in agreeing with Dempster and Pollard<sup>15</sup> that "the best hope of unravelling the roles of different factors in the population dynamics of animals, still rests in analysis of long-term, life-table data". The worry remains that, until we have a surer grasp of possible complications in the analysis, we cannot be certain we have gathered the appropriate data, no matter how long and carefully we have toiled in the field. □

# Big whorls do have little whorls

Ian Stewart

IN 1922 Lewis Fry Richardson wrote *Weather Prediction by Numerical Process*, and it won him election to the Royal Society. For 20 years it was considered disreputable, because of problems with the numerical methods proposed, but by 1955 it had become a classic. It contains a much-quoted parody of Jonathan Swift:

Big whorls have little whorls,  
Which feed on their velocity;  
And little whorls have lesser whorls,  
And so on to viscosity  
(in the molecular sense).

This is the famous Richardson cascade, a descriptive theory of turbulence. Although the mechanism is intuitively attractive, the experimental evidence in its favour has until now been largely indirect. Elsewhere in this issue (*Nature* 338, 51–53; 1989) Argoul *et al.* provide the first experimental geometric evidence for the cascade, and in particular for Benoit Mandelbrot's suggestion that the process is fractal.

If a drop of ink is placed in a jar of water, it creates a vortex ring as it falls. The ring acquires corners, from which smaller vortices break off. The process repeats to form a tree-like structure of

ever-smaller vortices. Each stage is geometrically similar to the previous one, but on a smaller scale — a structure characteristic of fractals. Richardson's idea is that something akin to this proliferating tree of vortices occurs in turbulent fluids. Large vortices break up into smaller vortices — presumably because they are unstable — which themselves break up into still smaller vortices.

The total energy is reduced by viscous friction, but the energy loss is slow to begin with. It becomes much more rapid as the size of vortices decreases, hence Richardson's parenthetical remark. Thus the energy of the fluid cascades into ever-smaller vortices until it is damped out by viscosity.

This suggestion is not Richardson's alone. Similar ideas go back to L. Prandtl, G. I. Taylor, and the statistical theory of turbulence of A. N. Kolmogorov (see A. A. Townsend, *The Structure of Turbulent Shear Flow*; Cambridge University Press, 1976). But how accurate a picture of turbulent flow is it? On physical grounds the idea is fairly plausible; but it has proved extremely difficult to make experimental measurements that are suf-

ficiently precise to justify the model in detail. There is also the difficult problem of extracting the intricacies of vortex dynamics from measurements of a few variables.

Argoul *et al.* overcome many of these difficulties by using a new analytical technique, the wavelet transform. The traditional Fourier transform represents a waveform in terms of a series of sine curves. Instead of sines, the new method represents the waveform in terms of localized solitary waves, more appropriate for nonlinear dynamics. The wavelet transform includes a scaling factor, and can therefore analyse fractal properties. In a sense, it renders visible the construction procedure for the fractal: in this case, the way that a vortex splits into smaller vortices. Successive splittings show up as successive branchings of the graphical representation of the transform.

Argoul *et al.* observe a tree-like branching pattern in high-velocity turbulence, similar to the construction procedure for one of the simplest fractals: the Cantor set. This set is universally misattributed: it seems to have been invented by Henry Smith in 1875, but Cantor drew attention to it in 1883 — citing Smith's work. It is obtained by repeatedly deleting the middle thirds of intervals, and thus has left-right symmetry.

As is made clear in the graphical

## Guanylate cyclases send out new signals

GUANYLATE cyclase has long had to play second fiddle to adenylate cyclase. Both enzymes were discovered in the wake of the identification, 30 years ago, of cyclic AMP as the intracellular mediator of the activation of glycogen metabolism by extracellular adrenaline. Adenylate cyclase and its product, cyclic AMP, have since been established as a much-used system of generating intracellular signals in response to the docking of hormones onto their cell-surface receptors. By comparison, the equivalent system of guanylate cyclase and cyclic GMP is under-employed and, perhaps consequently, often overlooked. But two separate strands of research are focusing renewed attention on the system.

Unlike adenylate cyclase, which is invariably part of the cell membrane, guanylate cyclase can be either membrane-bound or in soluble form in the cell cytoplasm. The membrane form has been intensively studied since the discovery, in the past few years, of the family of atrial natriuretic peptides (ANPs), which use cyclic GMP to mediate their signals that result in the excretion of sodium (natriuresis) and water, and in vasodilation. There has been mounting evidence that the receptor for ANP is, itself, a membrane form of guanylate cyclase. On page 78 of this issue<sup>1</sup>, Michael Chinkers *et al.* provide the ultimate evidence: the complementary DNA

for the enzyme from rat brain, when expressed in cells, has both guanylate cyclase and ANP-binding properties.

The deduced sequence of the enzyme is consistent with the obvious notion that the ANP-binding portion is on the exterior surface of the membrane and the guanylate cyclase on the interior. The sequence of the cyclase portion has considerable similarity with a membrane form of guanylate cyclase that mediates responses of sea-urchin sperm to peptides released by eggs. This observation is hardly surprising, as a complementary DNA for the sperm enzyme<sup>2</sup> was used as the probe to isolate the rat brain complementary DNA.

More interestingly, the sequence of the guanylate cyclase portion of the rat brain membrane enzyme has considerable similarity with the only sequence available for a soluble form of guanylate cyclase<sup>3</sup>, although Chinkers *et al.* conclude that the latter must be the regulatory, rather than the catalytic, subunit of the soluble enzyme.

One striking feature of the soluble enzyme not shared by the membrane form is that it contains a haem group. Some evidence has suggested that it is by interacting with the haem that endothelium-derived relaxing factor, now known from the work of Salvador Moncada and his colleagues<sup>4</sup> to be nitric oxide, activates the soluble guanylate cyclase of smooth

muscle, thereby generating the cyclic GMP that mediates muscular relaxation.

That observation created a flurry of interest and a subsequent broadening of its relevance. It is now known that L-arginine is the endogenous precursor of nitric oxide in endothelial cells<sup>5</sup> and in macrophages<sup>6</sup>, where it is clearly an intermediate in the synthesis of nitrite, but will now also have to be investigated as a possible intracellular signal of macrophage activation by means of guanylate cyclase stimulation. Evidence has also emerged that nitric oxide (not positively identified) mediates the increase of cyclic GMP that follows the interaction of external glutamate with its receptors (of the NMDA type) on the surface of cerebellar cells<sup>8</sup>.

Whether or not guanylate cyclases are destined always to play second fiddle to adenylate cyclases in the events that orchestrate cellular responses to external stimuli, they seem certain to make themselves heard in the coming months.

## GEOCHEMISTRY

representation of their results, the Richardson cascade observed by Argoul *et al.* is asymmetric. In other words, during the cascade, each vortex splits into smaller vortices of different sizes. Moreover, the scaling factor does not remain constant throughout the process, so the particular Richardson cascade that they observe is not precisely self-similar.

Recall that every fractal has associated to it a number, its Hausdorff dimension, which measures how irregular it is. Typically this dimension is not a whole number. Introductions to fractal geometry tend to emphasize self-similarity — that apart from the scaling factor the object looks the same at different levels of detail — and define the dimension in terms of constant scaling. But this property is not a prerequisite for being a fractal. In particular the dimension can be defined for fractals that do not have uniform scaling features. On one popular definition a fractal is just a set whose Hausdorff dimension differs from its topological dimension; less technically, it must possess detailed structure on all scales. The simplest way to achieve this is to have the same structure on all scales — that is, to be self-similar — but there exist many fractals whose structure varies from one scale to another. To emphasize this feature, fractals that are not self-similar are often referred to as multi-fractals.

For a rough analogy, modify the Cantor–Smith construction. Instead of always removing the same proportion of the interval, first delete the middle third, then the middle quarters of the remaining subintervals, then middle fifths, sixths, sevenths and so on. Because the deleted proportions vary, there is no true self-similarity, so the modified Cantor–Smith set is a multi-fractal. And to introduce asymmetry, delete intervals that are not centrally placed.

Thus there now exists experimental evidence for the fractal nature of turbulence, clarifying details of the fractal structure, and using this to show that the splitting of vortices is asymmetric and only approximately self-similar. These are features that must therefore be incorporated into any realistic model of the Richardson cascade, or deduced from any more detailed theory of turbulence. These are important results. However, the theory that they confirm is purely phenomenological. The Richardson cascade describes features of turbulent flows — but it does not derive them from the equations of fluid motion. Although fractals are typically associated with chaos in non-linear dynamics — apparently random motion in deterministic systems — these new results bear only indirectly on the relation between turbulence and chaos. □

# Tales of a lost magma ocean

Laura Garwin

CURRENT models for the formation of the terrestrial planets from the dust and gas of the solar nebula postulate a growing population of planetesimals, which in the final stages of accretion may have included about 100 Moon-sized bodies, ranging up to a few the size of Mars. Collisions between these proto-planets have been invoked to explain anomalies in the present-day Solar System, such as the retrograde rotation of Venus, the exceptional tilt of Uranus and the very high density of Mercury (see the recent News and Views article by G. Stewart, *Nature* 335, 496–497; 1988). Closer to home, the

not obvious that this energy will be transferred efficiently to the Earth, or distributed uniformly within it. Jay Melosh (University of Arizona) addressed this question by considering the heating caused by shock waves propagating away from the point of impact. His numerical calculations give temperature rises of 3,000–4,000 K throughout the Earth's mantle for an impactor whose initial velocity  $v$  (at large separation) is 7.8 km s<sup>-1</sup>; for  $v=0$ , at least half the mantle (the hemisphere adjacent to the impact) is heated this strongly. Given a mantle liquidus temperature of about 3,000 K,

even an initially cold Earth would have a completely or substantially molten mantle after the impact.

Independent calculations presented by Al Cameron (Harvard-Smithsonian Center for Astrophysics) yield similar results, and also indicate that the Earth's surface temperature would remain very high for thousands of years, as the rock-vapour atmosphere created by the most intensely heated material (see figure) accreted onto the Earth's surface. The mantle could

Computer simulation of the impact of a Mars-sized body with the Earth, showing the configuration about 80 min after initial contact. Rock particles are in shades of red and yellow, iron particles in blue and green. Lighter shades denote higher internal energy (a measure of the degree of heating or compression following impact).

orbital characteristics of the Earth–Moon system can also be explained by a ‘giant impact’ — in this case, a glancing collision between a Mars-sized body and the proto-Earth, with the Moon forming from the debris of the impact. Elsewhere in this issue (*Nature* 338, 29–34; 1989), H.E. Newsom and S.R. Taylor outline the consequences of such an event for the bulk chemistry of the Earth and Moon, and conclude that the hypothesis is cosmochemically plausible. But given the enormous energy involved in such a collision, might we not expect to see some record of it preserved in the Earth's present structure? A recent conference\* brought impact modellers together with those willing to speculate about conditions on the earliest Earth, to examine the evidence for or against the giant impact hypothesis.

The total energy available from the impact of a Mars-sized body on the proto-Earth is of the order of  $5 \times 10^{31}$  joules — enough to raise the temperature of the entire Earth by about 10,000 K. But it is

remain molten for even longer times, if enough volatiles re-accreted to the Earth to form a dense atmosphere.

The feldspar-rich highland rocks of the Moon are thought to have crystallized from a ‘magma ocean’ more than 100 km deep; if the Earth had its own magma ocean, where are its crystallization products? Unlike the Moon, the Earth is tectonically active, so one would not necessarily expect the products themselves to have survived. But a central tenet of modern geochemistry is that whenever crystals separate from a melt, either during melting or crystallization, a characteristic imprint is left on the chemistry of the melt and crystals. This arises because some elements (the incompatible, or trace, elements) fractionate preferentially into the melt, whereas others prefer the solid phases. A melt can crystallize to a solid of exactly the same composition only if the crystals remain in continuous contact with the melt, so that the chemical system is closed, or if all elements show no preference between crystals and melt (all partition coefficients are unity).

Given the bulk composition of the

\*Conference on the Origin of the Earth, Berkeley, California, 1–3 December 1988.

Earth's mantle, the depth (pressure) and temperature range of the molten layer, and partition coefficients for diagnostic trace elements between the melt and the minerals that would crystallize from it at those pressures and temperatures, it should be straightforward to calculate the effects of a crystallizing magma ocean on the trace-element contents of the minerals involved. This is the approach taken by Ted Ringwood (Australian National University), who has measured high-pressure partition coefficients for various elements, and used them to model the crystallization of magnesium-perovskite from a pyrolite melt. He concludes that a primitive crust would have formed, which was strongly enriched in some elements and relatively depleted in others.

As a result, certain pairs of elements (for example, lutetium and hafnium) would be strongly fractionated relative to one another; yet Ringwood noted that the oldest minerals known ( $4.2 \times 10^9$ -year-old zircons) have chondritic (undifferentiated) Lu/Hf ratios. He concluded that there could not have been a terrestrial magma ocean, unless the Earth was re-homogenized by  $4.2 \times 10^9$  years ago, removing all trace of its existence.

This seeming contradiction between Ringwood's experiments and the existence of a substantially molten early Earth was the subject of much controversy, as other speakers invoked independent evidence for a global magma ocean, or questioned the assumptions and experimental data behind Ringwood's model. Carl Agee (University of Bayreuth) addressed the problem of obtaining a terrestrial upper mantle of peridotitic (olivine-rich) composition from a primordial Earth with the more silica-rich composition of the CI chondrites (primitive meteorites which are thought to represent the composition of the solar nebula). A simple mass-balance argument shows that upper-mantle peridotite can be formed from a CI composition by subtraction of Mg-perovskite and addition of olivine — a combination that can be achieved by flotation of olivine and settling of perovskite crystals in a mantle molten to at least 1,000-km depth. Agee suggested that the observed partition coefficients for elements such as Al, Ti, Hf, Lu, Zr, Sc and Sm were consistent with the 30 per cent fractionation of perovskite required by his mass balance, but this point was hotly contested by Ringwood. Mike Drake (University of Arizona) considered that the addition of 30 per cent olivine would result in substantially non-chondritic ratios of Sc/Sm, Ni/Co and Ir/Au, which are not observed.

There was much debate concerning the reliability of partition coefficients measured at very high pressure — the experiments are difficult to perform, and perhaps even more difficult to interpret —

and about their application to chemical systems more complicated than those of the experiments. But Al Hofmann (Max Planck Institute, Mainz) made the general point that the partition coefficients are bound to deviate from unity, "whether you measure them or not". What must be explained is the general lack of fractionation of trace elements (preservation of chondritic ratios), in the face of a major-element composition so different from chondritic that significant differentiation must have occurred.

In an illustration of the principle that "for each geochemist there exists an equal and opposite geochemist", Herbert Palme (Max Planck Institute, Mainz) pointed out that we do not know that the Earth started out with a CI chondrite composition. He argued that, if the upper mantle is representative of the entire mantle, the Earth's bulk composition is closest to that of the CV chondrites, which have lost silica relative to the CIs, probably in the solar nebula. This proposal avoids the need for extensive differentiation of the Earth's mantle, although there may be problems in detail with CV chondrite as a parent material for the Earth.

In contrast, Don Anderson (California Institute of Technology) put his faith in "seismic chemistry" as a more reliable guide to the composition of the bulk mantle than samples of upper-mantle

peridotite. He cited density and seismic-velocity data supporting an FeO content of about 14 per cent for the lower mantle, as compared with values of 8–12 per cent for the upper mantle. Although this FeO content is high compared to chondrites, it is comparable to a recent measurement for the solar photosphere (H.H. Breneman & E.C. Stone *Astrophys. J.* **289**, L57; 1985), and to the values inferred for the Moon and Mars. So this line of argument forces us once again to explain the Mg-rich upper mantle by large-scale chemical differentiation, and to confront the paradox of unfractionated trace elements.

Returning to the question that prompted the conference, it seems that mantle geochemistry cannot (yet?) be used to support or contradict the giant impact hypothesis. As Anderson emphasized, Ringwood's experiments (or, more generally, partition coefficients substantially different from unity) do not rule out melting; they only rule out fractionation at mantle pressures. Thus, if crystals could be kept in contact with the melt throughout crystallization, for example by entrainment in a turbulently convecting flow (W. B. Tonks, University of Arizona), a global magma ocean could come and go without leaving any imprint on the chemistry of the mantle. □

Laura Garwin is Physical Sciences Editor of Nature.

## POLYMERS

# Surface segregation of blends

A. M. Donald

Ask physicists what length scale they associate with surface phenomena and they are likely to come up with a value of 1 nanometre or less. But for polymers, because of their large chain length, the distance associated with a surface 'monolayer' is much larger, and corresponding timescales much longer than for simple atomic or molecular systems. Thus polymer systems could be ideal for experimental tests of recent theoretical predictions concerning wetting and surface phase transitions in binary mixtures, which relate directly to the precise composition of the surface. Few experiments have yet been carried out to look at the surface composition of polymer blends (miscible two-component systems) but new results from E. J. Kramer and colleagues<sup>1,2</sup> indicate that a very marginal difference between the surface energy of polystyrene and its deuterated form gives rise to a dramatic enrichment of the latter at the surface relative to the bulk composition. It is to be expected that even more striking effects could be seen with blends containing chemically distinct polymers.

Few polymer pairs are miscible. This can be explained in terms of the small

entropy of mixing relative to the total entropy: the number of configurations in a long chain system is already so large there is little to be gained by mixing in a second species. Thus mixing will occur only when there is a sufficiently favourable specific (enthalpic) attraction between the two components. A particularly simple blend system arises when the two components differ only by isotopic substitution, for example of all the hydrogen atoms (<sup>1</sup>H) on the chain by deuterium (<sup>2</sup>H). Polystyrene blends become miscible above a critical temperature (176 °C for the molecular weights used in the study of Kramer and co-workers), and thus in the bulk there is a homogeneous distribution of the two components at temperatures greater than this.

But what happens in the vicinity of a surface of a miscible blend? If the two components have different surface energies, then a driving force exists to permit the component of lower surface energy to segregate preferentially at the surface — as is known to occur for binary alloys and liquids of small molecules. The technique that Kramer and co-workers have used, forward recoil spectrometry

Volume fraction of deuterated polystyrene (d-PS) blended with polystyrene as a function of depth, after annealing at 184 °C for 5 days (initial volume fraction 0.15). Shaded area, surface excess. (From ref. 1.)

(FRES), is well-suited to tackle this problem for isotopic blends, because it permits the relative amounts of  $^1\text{H}$  and  $^2\text{H}$  to be measured as a function of depth.

In the technique, high-energy (about 3-MeV) helium ions are incident on the sample at a glancing angle. When these ions collide elastically with the  $^1\text{H}$  and  $^2\text{H}$  nuclei, the nuclei are ejected and subsequently detected; a foil screens the scattered  $\text{He}^{2+}$  ions from the detector. Kinematic theory predicts the energy with which nuclei at the surface are ejected (the energy separation between the two types of nuclei is about 0.5 MeV). For nuclei below the surface, energy is lost owing to frequent collisions with electrons, and so the peaks associated with the two types of ions are spread to lower energies, with a peak shape determined by the composition profile. The depth resolution of the technique (about 80 nm) is largely limited by the straggling in the stopper foil.

This technique was originally developed to look at  $^1\text{H}$  and  $^2\text{H}$  profiles in metal<sup>1</sup>. More recently Kramer's group have extended it to look at various diffusion problems in isotopic polymer blends. For the case of preferential segregation of one component at a free surface, the resolution is insufficient to reveal the detailed structure, but Kramer and colleagues can observe a marked enhancement in the average concentration of deuterated polystyrene relative to the bulk concentration (see figure). From the dependence of the surface excess on the bulk composition, the authors calculate, using an analysis developed by Schmidt and Binder<sup>4</sup>, that the difference between the surface energy of the protonated and deuterated forms of polystyrene is a mere  $8 \times 10^{-5} \text{ J m}^{-2}$  — far too small to be measured directly.

But clearly, if such a weak effect in polystyrene (which arises from differences in polarizability between  $\text{C}-^1\text{H}$  and  $\text{C}-^2\text{H}$  bonds) leads to such a strong surface enhancement, then for polymer blends of practical importance, which typically contain components with very different chemical properties, the surface enhancement should be striking.

Because it is the blend's surface which

determines many of its properties — environmental resistance, wetting and friction, for instance — this finding is not simply of theoretical interest. In addition the surface properties may vary with the route of blend preparation — that is, whether this surface enrichment has time to become established.

The FRES technique is currently being refined by Kramer and co-workers, who are looking at ways the use of a stopper foil can be avoided to improve the resolution. They now claim<sup>2</sup> to have a detector with resolution better than 35 nm — capable of examining the composition profile in considerable detail. Other surface techniques with high spatial resolution are also becoming available for polymer systems. These include secondary-ion mass spectroscopy and X-ray photoelectron spectroscopy, but the one that looks most promising and is attracting most attention is neutron critical reflectometry. Many laboratories, including the Rutherford-Appleton, are now setting up

appropriate spectrometers (see ref. 5 for the first application to a polymer interface). Although this technique cannot provide such a direct measure of chemical composition as FRES, its high resolution (estimated to be about 5 Å) will permit checking of any hypothesized distribution of components. In this sense it can be regarded as complementary to FRES. A burst of activity in the field of polymer surfaces therefore seems likely, with implications for an improved understanding of surface phenomena at both the pure and applied levels. □

#### NATURAL SELECTION

## Why do plants produce so many more ovules than seeds?

Deborah Charlesworth

MANY flowering plants produce far fewer mature fruits than flowers, and fruits often contain fewer seeds than the number of ovules that were available for fertilization. A striking example of a plant in which there is a low value of the number of seeds produced compared with the number of available ovules is the shrub *Dedeckera eurekaensis* described by Wiens *et al.* on page 65 of this issue<sup>1</sup>.

One obvious possibility, which seems to be at most only part of the story, is that flowers sometimes do not get enough pollen to fertilize all the ovules. The supply of pollen (or uncertainty of its receipt) can often limit the chance that a flower sets a full complement of seeds<sup>2,3</sup>. In self-incompatible species, pollinators may deposit the plant's own pollen on its stigmas, perhaps clogging up the flowers' stigmas so that they cannot later be fertilized<sup>4,5</sup>. Similarly, pollen from the wrong species might reduce flowers' chance of fertilization. In self-compatible species, ovules fertilized by self pollen may yield inviable seeds so that seed production in nature may be low. P 36,657

In many cases, however, including that of *D. eurekaensis* described in this issue<sup>1</sup>, pollen supply does not seem to be the main limiting factor for fruit set<sup>6</sup> or seed set per fruit<sup>7</sup>. Because it is also frequently found that many fruits and seeds initiated are aborted even when plenty of compatible pollen is deposited on the stigmas<sup>8–10</sup>, the role of the 'excess' flowers and ovules

cannot be to increase female fertility, and fruit abortion probably indicates limitations in the amount of resource available for the (presumably) costly process of fruit maturation<sup>11</sup>. Under natural pollination conditions, outcrossing species generally have lower seed/ovule and fruit/flower ratios than do inbreeders, and so do long-lived woody species<sup>9,12,13</sup>. The existence of these clear between-species differences suggests that these ratios are probably not just consequences of the local environmental circumstances in which the particular plants studied were growing. Interpreting such comparative data is difficult<sup>14,15</sup>, in this case especially so because the characteristics of the different species are correlated: for example, annual species include a much lower fraction of outcrossers than do perennials<sup>13</sup>. Thus the low ratios of perennials might result from their more outbreeding population structure, compared with annuals, rather than from their living longer. The patterns seen can be greatly clarified by experimental data, which can help in the assessment of the contributions of the two most plausible types of explanation.

The first explanation is based on the idea from the theory of life-history evolution that perennial species must allocate resources between the competing functions of pollen and ovule production at the time of flowering (which probably determine later expenditures necessary to mature the fruits) and storage of nutrients

Mean fitness of a completely outcrossing population at its equilibrium under mutation to deleterious partially recessive alleles at many loci, compared with the corresponding mean fitness of populations reproducing only by self-fertilization, with different mutation rates per diploid genome. The outcrossing mean fitness does not depend on the type of selection or the values of the selection parameters, so only a single line is shown. For the selfing cases, results for various values of the selection coefficient of a mutant allele ( $s$ ), and the dominance coefficient ( $h$ ) are: black circles,  $s=0.5$ ,  $h=0.5$ ; open circles,  $s=0.2$ ,  $h=0.2$ ; squares,  $s=0.01$ ,  $h=0.2$ .

for growth and survival to the next season; they are therefore expected to have a low rate of reproduction and thus produce few seeds per unit mass of plant in any one season<sup>16</sup>. Why then do they have many flowers and ovules? This can be accounted for in terms of the male fertility component of fitness through pollinator attraction<sup>17,18</sup>. It is then surprising that plants do not frequently produce some flowers with purely male function and become andromonoecious. Total loss of female function of flowers may be disadvantageous because of uncertainty of the pollination process; unless each flower has a high chance of getting fertilized, or unless fruits are very costly of resources (for example very big), maximum-realized fertility cannot be achieved from a few flowers<sup>19,20</sup>.

Another interpretation is that outcrossers suffer high genetic loads, causing many fertilization products to abort early in development<sup>21</sup>. (Genetic load is the relative lowering of the mean fitness of a population compared with the fitness of the best possible genotype.) Genetic loads are thought to result mainly from mutation to harmful partially or fully recessive alleles such as recessive lethals, and possibly also to alleles maintained by heterozygote advantage<sup>22</sup>. The second type of genetic load is least with outcrossing and increases somewhat with self fertilization (selfing), presumably because heterozygote advantage helps maintain variation in populations even though homozygotes produced by selfing are at a disadvantage. This type of gene action cannot therefore explain the low fecundity of outcrossing species.

With genetic load resulting from mutation, mean fitness increases as selfing increases because the equilibrium fre-

quences of deleterious alleles are reduced. The total genetic load in a wholly selfing population can be much lower than in a completely outcrossing population when the mutation rate is high, so that individuals in the outcrossing population are heterozygous for many mutant alleles depressing fitness (see figure). It seems unlikely that all this load will be expressed in the earliest stages of development so as to be detectable as reduced seed maturation, but this view might be wrong, as this is an important developmental stage. It is not known what proportion of plant genomes are expressed in the seed stage; certainly many mutations are known that affect seed (embryo and endosperm) characters<sup>23,24</sup>.

If mutational load contributes to the loss of fertilization products in outcrossing plants, the abortion of individual seeds will be determined by the zygote genotypes; it should be random within fruits, and its frequency should be affected by the maternal and paternal parents, and by interaction between them<sup>25</sup>. Furthermore, in outcrossing populations with mutational load including partially or fully recessive alleles, strong inbreeding depression would be expected; in *D. eur-ekensis* Wiens *et al.* find that outcrossed flowers produce more mature seeds than selfed ones, but the difference is not statistically significant. This hypothesis could also account for the correlation between longevity and low female fecundity if long-lived species have higher mutation rates, as has recently been argued<sup>26</sup>. □

## Surprising damp

DAEDALUS once devised an anti-condensation paint for kitchens and bathrooms. It was based on the 'hydrogel' polymers used for soft contact lenses; these readily absorb water, swelling somewhat as they do so. A hydrogel paint can thus absorb sudden peaks of condensation, and slowly breathe it out again as vapour in periods of low humidity. With the walls and ceiling of the whole room as an absorption surface, many litres of condensation can be taken up.

The problems began when Daedalus tried to colour his new product for the domestic market, by mixing it with a rather hastily formulated emulsion paint. In a cold, damp room the new mixed paint certainly took up water vapour very efficiently. But when the room was warmed up to reduce its relative humidity, condensation actually oozed from the painted surface and ran depressingly down the walls. It turned out that the liquid emulsion droplets dispersed in the paint had solidified in the cold test room. On warming up, they melted again, expanding strongly as melting vegetable oils do. The water-swollen hydrogel was thus suddenly and forcefully pressurized from within, and its loading of liquid water was squeezed out of it by reverse osmosis. Daedalus had invented a condensation generator.

DREADCO's marketing department soon rose to the challenge of this new product. Wet Paint® is being aimed at the car and vehicle market. The weekly wash and polish beloved by devout car-owners is mainly symbolic: corrosion starts at internal seams and surfaces no owner can reach. But a Wet-Painted car will never need to be cleaned at all. Every night, as the temperature falls and humidity rises, its surface will absorb water vapour; every day, as the temperature rises, it will weep the water out again as a liquid. Coming out of the paint surface itself, the exuded water will clean far more efficiently than any external spray. Dirt and road salt will simply be dislodged from beneath and floated away. Applied to trains, houses, bridges, and many other external structures, Wet Paint will keep grime, mould and graffiti at bay. The whole urban environment will be wonderfully smartened up.

Some technical problems remain to be solved, of course. During its pressure-exudation phase, Wet Paint tends to weep not only at its outer surface, but also at its inner one, thus pumping itself forcefully off the wall. Reliable bonding to substrate or undercoat is needed. On the other hand, DREADCO's cosmeticists hope to apply this principle in a new and powerful moisturizing cream. Unique among such preparations, it will take up moisture from the air and force it into the wearer's skin under many atmospheres of hydraulic pressure.

David Jones

# The pulsar inside SN1987A

SIR—The discovery<sup>1</sup> of a pulsar inside the remnant of supernova 1987A is not in itself surprising. The initial neutrino burst<sup>2,3</sup> suggested the formation of a neutron star, and the low-energy X-ray flux (6–16 keV) observed by Ginga<sup>4</sup> has been interpreted as evidence for an active pulsar. Apart from fluctuations on time-scales of days, the soft X-ray flux has remained constant at about  $6 \times 10^{36}$  erg s<sup>-1</sup> since its first appearance in January 1988 (Y. Tanaka, personal communication). The harder emission, above 20 keV, has declined in the past few months<sup>5</sup>, in accordance with the radioactivity model<sup>6</sup>.

We have suggested that the soft X-ray flux could be synchrotron emission from a non-thermal nebula, fed by the remnant pulsar at a rate of about  $10^{38}$  erg s<sup>-1</sup> in the form of relativistic particles and magnetic field<sup>7,8</sup>. The emission could be detected if the supernova envelope had undergone early fragmentation, shortly after the explosion. The pulsar input would amount to a significant fraction of the present bolometric luminosity of the supernova, and deviations in the decay of the light curve should be expected: preliminary indications of an extra energy input may already be available<sup>8</sup>.

The finding of the pulsar lends strong support to these ideas. The properties of the pulsar, however, are rather surprising, especially its extremely short period and the small value of the surface magnetic field.

The strength of the magnetic field at the light cylinder radius,  $\sim 2.4 \times 10^9$  cm, where field lines corotate with the pulsar would move tangentially at the speed of light, is bracketed by the requirements that the electromagnetic energy output be less than SN1987A's present bolometric luminosity,  $2.1 \times 10^{38}$  erg s<sup>-1</sup>, and more than the pulsed optical luminosity,  $6.4 \times 10^{35}$  erg s<sup>-1</sup>. Thus  $2.3 \times 10^9$  G  $< B < 4.2 \times 10^7$  G, corresponding to a surface field between  $3.3 \times 10^7$  and  $6 \times 10^8$  G if dipolar geometry is assumed.

The SN1987A pulsar thus belongs to the class of weakly magnetized, rapidly rotating objects for which a 'recycling'

scenario is accepted as canonical. Clearly, we have here first-hand evidence that at least some objects of the class are 'primordial'<sup>9</sup>. One may then wonder about the size of the millisecond pulsar population, because a new production mechanism has been found and since the radio surveys performed so far have not covered adequately the submillisecond range. Also, we note that, if pulsars such as this one are born frequently, their magnetic field cannot be amplified up to  $10^{15}$  G later on by thermoelectric instabilities<sup>11</sup>, because this would entail a huge, delayed release of rotational energy, for which we have no astrophysical evidence.

In the discovery observations a weak sinusoidal modulation of the pulsar frequency is noted. If confirmed and interpreted at face value as evidence for a binary companion, the modulation would imply a companion mass of  $\sim 10^{-3}$  times the mass of the Sun. At any rate, whether the claimed modulation is real or only an upper limit, the interpretation that the soft X-rays from SN1987A result from accretion<sup>12</sup> appears unlikely.

Concerning the nature of the optical radiation mechanism, we note that the brightness temperature of the observed pulses, even including the entire speed-of-light surface, corresponds to an electron Lorentz factor of at least  $1.6 \times 10^4$ , whereas the Lorentz frequency in the minimum magnetic field is already  $6 \times 10^{12}$  Hz. Then, in order to satisfy the thermodynamical constraint, one has to invoke either synchrotron radiation by protons, or by coherent processes, or, perhaps, electron synchrotron radiation well beyond the speed-of-light distance.

Another puzzle concerns the variations observed in the average pulsar optical luminosity. One could imagine a single physical cause for them and for the 8-h period of the frequency modulation, if the latter is confirmed. More likely, they could be attributed to the effect of the inhomogeneous nebular medium, in the same way as postulated for the fluctuations of the soft X-ray flux<sup>7,8</sup>. Although homogeneous models of the supernova envelope become transparent to optical radiation a few months after the explosion<sup>13</sup>, the optical spectra of SN1987A still show clear signs of opacity effects, probably due to bound-bound and bound-free transitions of metals (E. Oliva, personal communication); if the envelope material is clumpy, and if the clumps have some non-radial motion, temporary occultations of the pulsar are a reasonable possibility.

Finally, we recall that a rotation frequency of 2 kHz is close to the hard limit of the virial theorem, and strains the predictions of certain stellar interior models on the onset of non-axisymmetric

instabilities<sup>14</sup>. The mere fact that such a rotation is observed after two years implies a mass quadrupole moment smaller than  $5.3 \times 10^{40}$  g cm<sup>2</sup>. The above limit corresponds to a gravitational wave luminosity of  $6.1 \times 10^{14}$  erg s<sup>-1</sup>, which still would be the main energy output channel by a very large margin. A measurement of the first and second derivatives of the period would establish the relative importance of gravitational radiation losses.

## Hair light guide

SIR—During studies on the staining of whole plucked hairs for use in biological dosimetry, we have observed that grey hairs illuminated at one end emit light at the other (J. Wells, *Stain Technol.* **63**, 189; 1988). An example of this phenomenon is illustrated in the figure. A 6-mm-long grey hair was mounted through a piece of card, ensuring that light could not

pass between the card and hair, and the card was placed on a microscope stage and illuminated from below. Of the 2 mm of hair protruding through the card, only the cut end emitted sufficient light to be seen down the microscope. Reduction in light intensity was noted with increased hair length but by far the most important factor was hair colour; little or no light was transmitted by brown hair.

Thus, grey hair acts as a natural fibre optic which can transmit light to its matrix, the follicular epithelium and to the dermis. Whether light transmission down hairs affects skin and hair needs investigation.

## DNA helical repeats

SIR—The recent paper, "The helical repeat of double-stranded DNA varies as a function of catenation and supercoiling", by Wasserman *et al.*<sup>1</sup> gives the misleading impression that the authors have solved the fundamental problem of the partition function between twist and writhe in supercoiled DNA. In fact, the authors did not measure the DNA helical repeat,  $H$  (ref. 2), but a newly defined parameter,  $h$  (ref. 3).

Whereas  $H$  is uniquely determined by the three-dimensional structure of a given DNA molecule,  $h$  measures the relationship between the DNA and a chosen reference surface<sup>3</sup>, and is therefore related to DNA structure only indirectly. Thus, the differences in  $h$  calculated by Wasserman *et al.* correspond to changes in the relationship between the DNA and a reference surface rather than to changes in the internal structure of the DNA. The results of Wasserman *et al.* therefore have no relevance to the energetic constraints on DNA deformation. Furthermore, although the parameter  $h$  has a clear biological meaning when it relates DNA to a real surface, its significance becomes doubtful when the surface is only imaginary.

COZZARELLI *ET AL.* REPLY—For a DNA whose axis lies on a surface, real or virtual, there are two related measures of the turning of the double helix: twist ( $Tw$ ), which measures a component of the rotation of one strand about the axis, and winding number ( $\Phi$ )<sup>3</sup>, which is the sum of the periodic exposures of either strand away from the surface. The helical repeat of a DNA with  $N$  base pairs has been defined in two different ways, namely  $(N/\Phi)$  and  $(N/Tw)$  or  $h$  and  $H$ , respectively, in the nomenclature of Stasiak *et al.* Both are valuable measures of DNA structure and differ only when DNA is supercoiled.

Contrary to the assertion of Stasiak *et al.* however,  $h$  is often the property of biological significance. It is also much more easily measured. The parameter  $h$  defines the sequence periodicity of nucleosomal DNA (ref. 4) and the phasing of protein-binding sites, and is, in fact, most commonly measured by the accessibility of DNA to chemical or enzymatic probes. In our experiments,  $(N/\Phi)$  not

$(N/Tw)$  is determined by the catenane-induced supercoiling<sup>1</sup>. Supercoiling derived from catenation, linking number deficit, and the wrapping of DNA around histones, in all cases, leads to a change in  $h$  (and also  $H$ ); it is thus obviously incorrect for Stasiak *et al.* to assert that  $h$  has no relevance to DNA structure or deformation. Stasiak *et al.* make an additional error; Wang<sup>2</sup> did not distinguish  $H$  from  $h$  as he used relaxed DNA, for which the two are equal.

## Cystic fibrosis

SIR—Kitzis *et al.*<sup>1</sup> confirm preliminary reports<sup>2</sup> of a segregation distortion of cystic fibrosis (CF) alleles with the sex of carriers. They use informative linked DNA markers to track CF alleles in families where there are carriers of the disease and count the numbers of carriers and non-carriers amongst unaffected siblings. The male/female ratio is as expected (1/1) and the carrier/non-carrier ratio follows mendelian expectation (2/1). But the male/female ratio for CF carriers is 1.21/1.0 (with a complementary 1.36/1 female/male ratio for non-carriers). We bring to your attention work reported by Gedschold *et al.*<sup>3</sup>, which we believe indirectly supports this segregation distortion phenomenon. These authors analysed questionnaires from a population-genetic study<sup>4</sup>, to show that for East German CF families, female carriers had more sibs (1.99 on average) than male carriers (1.66).

These two findings are remarkably consistent; the segregation distortion will generally lead to female carriers being found in larger sibships than male carriers. Using a male/female carrier ratio of 1.21/1.0, the likelihood ratio of families ascertained through one female carrier with 1.99 unspecified sibs producing  $n$  carrier sibs to families with one male carrier and 1.66 unspecified sibs producing  $n$  carrier sibs is almost unity (that is, ignoring constant terms,  $1.21 \times 1.66/1.0 \times 1.99 = 1.0093$ ).

Hence, we conclude that the segregation distortion of CF alleles with sex explains the differences in sibship sizes for male and female carriers. Linkage dis-

equilibrium between the CF allele and alleles detected by DNA probes can be used to modify prior risks for individuals seeking carrier determination/exclusion<sup>5</sup>. Perhaps, now that the segregation distortion is confirmed, risk calculations should include the consultant's sex.

## Unhealthy genes

SIR—In a recent review article (*Nature* **336**, 435; 1988) Kondrashov asks whether future generations will gradually have less healthy genes. I found his article particularly interesting as I have recently started a debate in Norway concerning this problem.

The rate of mutation of human genes is no less than before. In industrialized societies, where the combination of medical care, lifestyles and reproduction strategies have decreased the selection for robust individuals, unwanted mutations will therefore be expected to accumulate.

The known genetic diseases represent only a small part of this problem, simply because they represent only a few specific mutations in a very limited number of genes. We have about 100,000 different genes (plus a large amount of DNA that influences gene activity) and each gene can mutate in many different ways. Some mutations are lethal, and therefore easily selected against, but most are probably either relatively neutral or slightly detrimental and do not cause any overt disease that can be traced to a specific mutation.

As a consequence we must, in the long run, expect an increased frequency of various health problems, implying that an increasing fraction of resources will need to be directed to health care.

I believe that an effort should be launched to evaluate the problem. The most important question is how fast the deterioration takes place. Depending on the outcome of this evaluation, it may be worth investigating possible means of dealing with the problem.

Kondrashov points out that the increase in unhealthy genes is a practically irreversible process. The irreversibility lies in the fact that we are dealing with humans and not animals, for which relevant selection programmes would be easy to implement.

# SFA-II Rapid Kinetics Accessory

For UV/Vis  
Spectrophotometers  
and  
Spectrofluorimeters

NEW FEATURES  
ENHANCED  
CHEMICAL RESISTANCE

Over 300 of these popular units have been sold throughout the world. The SFA-II uses the stopped-flow method to reduce the fastest half life measurable from several minutes to well under a second.

- Observed reaction mixture is just 10cms old
- Thermostatted and chemically inert flow circuit
- Can be fitted in seconds without tools
- Requires just 150µl per shot
- Universal cell for absorbance, fluorescence and CD measurements
- Small volume available  
—350µl dead volume

HI-TECH is a Registered Trademark since 1960

# Stopped and Quenched Flow

Hi-Tech Scientific manufacture the world's most successful and capable rapid kinetic instruments.

- Stringently economical with precious samples
- Empirical dead time of 600 microseconds
- Reaction rates in excess of  $2000\text{s}^{-1}$  can be routinely followed
- SpectraScan accessory is fast (90nm/ms) and sensitive
- Professional data acquisition and processing software
- Options for IBM, IBM compatible, Hewlett Packard and Apple
- Excellent fluorescence performance
- Microvolume available, 100µl dead volume

*The most complete record of a normal fault break, to date*

**Edgecumbe earthquake** A special issue of—  
The New Zealand Journal of Geology and Geophysics

This unique collection of 21 papers documents the total sequence of a recent significant (magnitude 6.3) earthquake.

The 1987 Edgecumbe earthquake produced a clear fault break, substantial deformation, widespread damage, and the strongest ground motion yet recorded in New Zealand.

Records from permanent seismographs and rapid action by seismologists and geologists have resulted in a complete document of seismological, geological, and engineering interest.

**Chirality** is an international journal devoted to the study of molecular asymmetry and its role in both biologically and non-biologically active molecules. This authoritative publication emphasizes the pharmacological, biological, and chemical properties of chiral molecules with a focus on drugs, pesticides, and other xenobiotics.

**Chirality** presents original papers reflecting recent research on the various aspects of chiral molecules, including their pharmacology, clinical pharmacology, toxicology and chemistry. The journal covers such specific topics as:

- the influence of chirality on pharmacokinetics (absorption, protein binding, biotransformation)
- the influence of chirality on pharmacodynamics (drug receptor interactions, pharmacological activity)
- the influence of chirality on clinical pharmacology (therapeutic index, bioavailability, adverse reactions)
- stereospecific synthesis
- stereoselective analysis
- preparative separation of chiral molecules
- the regulatory and legal aspects in the development, testing, and marketing of chiral compounds

In addition to original papers from leading researchers, **Chirality** publishes brief reviews, short communications, conference reports, and book reviews.

**Chirality** offers broad-ranging, timely coverage of this dynamic field, making it essential reading for pharmacologists and clinical pharmacologists, analytical, medicinal and clinical chemists, biochemists and molecular biologists and all scientists involved in the preparation, development and testing of chiral compounds.

**Subscription Information:** **Chirality: The Pharmacological, Biological, and Chemical Consequences of Molecular Asymmetry**, Volume 1, 1989, four issues at the rate of \$120.00. # Current, Authoritative Reading

## Food Analysis

### Modern Methods of Plant Analysis

Series editors: H.-F. Linskens, J. F. Jackson

Solar wind-ventilated dryer (After Takla 1978)

Volume 10

H.-F. Linskens, Erlangen; J. F. Jackson, Glen Osmond (Eds.)

### Plant Fibers

1989. 96 figures. Approx. 420 pages. Hard cover DM 328,-. ISBN 3-540-18822-3. (Reduced price for subscribers to the entire series DM 278,-.)

The analysis of all plant fibers important to plant structure or industrial utilization is treated, with special emphasis on cellulose, the industrially dominant fiber (wood, paper, etc.).

Volume 9

H.-F. Linskens, Erlangen; J. F. Jackson, Glen Osmond (Eds.)

### Gases in Plant and Microbial Cells

With contributions by numerous experts

1989. 88 figures, 29 tables. XXII, 352 pages. Hard cover DM 286,-. ISBN 3-540-18821-5. (Reduced price for subscribers to the entire series DM 244,-.)

Volume 8

H.-F. Linskens, Erlangen; J. F. Jackson, Glen Osmond (Eds.)

### Analysis of Nonalcoholic Beverages

With contributions by numerous experts

1988. 90 figures, 94 tables. XX, 412 pages. Hard cover DM 320,-. ISBN 3-540-18820-7. (Reduced price for subscribers to the entire series DM 278,-.)

Volume 7

H.-F. Linskens, Erlangen; J. F. Jackson, Glen Osmond (Eds.)

### Beer Analysis

With contributions by numerous experts

1988. 97 figures. XXIII, 304 pages. Hard cover DM 248,-. ISBN 3-540-18308-6. (Reduced price for subscribers to the entire series DM 213,-.)

Volume 6

H.-F. Linskens, Erlangen; J. F. Jackson, Glen Osmond (Eds.)

### Wine Analysis

With contributions by numerous experts

1988. 86 figures, 39 tables. XV, 381 pages. Hard cover DM 298,-. ISBN 3-540-18819-3. (Reduced price for subscribers to the entire series DM 254,-.)

## Earth Sciences

S. Heitz, University of Bonn

### Coordinates in Geodesy

1988. 20 figures. XII, 255 pages. Soft cover DM 58,-. ISBN 3-540-50088-X

In this book definitions and transformations are treated, based on the general principles of differential geometry for surfaces and three-dimensional Euclidean space, strictly using the tensor calculus. The broad approach applying general concepts of constructing and transforming coordinates allows clearly arranged solutions for all geodetic applications.

E. Groten, Darmstadt; R. Strauss, Wiesbaden

### GPS-Techniques Applied to Geodesy and Surveying

1988. XVII, 532 pages. (Lecture Notes in Earth Sciences, Volume 19). Soft cover DM 118,-. ISBN 3-540-50267-X

This work contains the proceedings of an international workshop held in April 1988 at the Technical University in Darmstadt, Germany. It presents a state-of-the-art description of GPS techniques applied to geodesy and surveying, with emphasis on monitoring time dependent phenomena.

J. H. Latter, Wellington (Ed.)

### Volcanic Hazards: Assessment and Monitoring

1989. 284 figures, some in colour. XIII, 625 pages. (IAVCEI Proceedings in Volcanology, Volume 1). Hard cover DM 178,-. ISBN 3-540-19337-5. (Reduced price for subscribers to the journal "Bulletin of Volcanology": Hard cover DM 142,40)

Special attention is devoted to the question of how surveillance of both active and inactive volcanoes can be carried out in different parts of the world. This compilation will prove useful not only for researchers in the field, but also for anyone required to deal with practical aspects of public safety in volcanic emergencies.

N. D. Naeser, Denver; T. H. McCulloh, Dallas (Eds.)

### Thermal History of Sedimentary Basins

Methods and Case Histories

1989. 197 figures. XIV, 319 pages. Hard cover DM 120,-. ISBN 3-540-96702-8

This volume presents the reader with the theory, methods of study, and applications of the major organic and inorganic indicators used to determine thermal history.

J.-P. Lefort, University of Rennes

### Basement Correlation Across the North Atlantic

Translated from the French by M. S. N. Carpenter

1989. 77 figures. XI, 148 pages. Hard cover DM 88,-. ISBN 3-540-18794-4

Major structural features are used in this study to reconstruct the links which existed between North America, Europe and Africa before the opening of the North Atlantic Ocean. The synthesis of geophysical and geochemical data as well as geological observations allows the recognition of the original geometry of the Grenvillian, Cadonian, Caledonian, Ligerian-Acadian and Hercynian foldbelts and the identification of ancient plate sutures.

# The rich and the irradiated

Daniel J. Kevles

**Uranium Frenzy: Boom and Bust on the Colorado Plateau.** By Raye C. Ringholz. W.W. Norton: 1989. Pp. 310. \$18.95. To be published in Britain in June, £13.95.

IN *Uranium Frenzy*, a tale of the modern American West, Raye Ringholz recounts the quicksilver dreams, leaden disappointments (and worse) brought about after the Second World War by the United States Atomic Energy Commission's desperate determination to encourage the establishment of a domestic uranium supply. The AEC, as the Commission was commonly known, offered prospectors a \$10,000 bonus for each discovery of a uranium lode and guaranteed to purchase ore production for ten years at a certain minimum price. The inducements helped to stimulate a boom in uranium prospecting, mining and production in the Colorado Plateau, the dry, unforgiving region where Colorado, Utah, Arizona and New Mexico conjoin.

The author is a longtime resident of the Plateau region and an experienced freelance author. She brings to her book a first-hand familiarity with the ambience of the boom years and information and anecdotes drawn from interviews — they form her principal sources — with many of the participants. Although attentive to the larger government policies that shaped the boom, she tells the tale by fastening on the stories of individual players, both winners (the prospectors and penny-stock jobbers who became millionaires overnight) and an array of losers. Some of the losers — the lucky ones — lost only their shirts. Others, found among the miners whose lungs were exposed to radon and its daughter products, came down, years later, with lung cancer.

Ringholz personifies the boom with Charlie Steen, who came to the Plateau, in 1949, as a young, rebellious and unemployed geologist to hunt for uranium. He searched for the ore in areas where conventional wisdom said it didn't exist and found a rich core sample of pitchblende when, in July 1952, he broke his last drilling bit at 197 feet. Charlie and his mother, Rose, who had grubstaked him, promptly formed the Utex Corporation to exploit the strike, joining with two partners, who put \$19,000 into the venture. In December 1953, Charlie and Rose bought their partners out, paying them \$3,272,000 for the Utex stock they had received for their \$19,000 investment slightly more than a year earlier.

By this time, the uranium boom was on in earnest. Moab, Utah, where Steen and his family had moved, had been a small, conservative, inbred town; now it pulsed with the traffic of Cadillac convertibles,

ore trucks and enormous Chevrolet station wagons. In 1952, the stock-salesman population of Salt Lake City had totalled 100 people working for 20 brokerages; by March 1955, it had reached 467 salesmen hawking their wares for 80 houses. The come-ons could be, to say the least, inventive. Squeeze the pitchblende, one

mining continued. The next year, the first death from lung cancer occurred among the miners on the Plateau.

Ringholz makes clear that the federal government dealt rather less decisively with the hazards of radiation to uranium miners than it did with those of stock fraud to uranium investors. Not that federal officials were unaware of the danger to the miners: in 1950, Duncan Holaday, a member of the United States Public Health Service, had begun a study of radiation levels in the mines. By 1952, he had produced a report showing that the levels — a median in 48 mines of 3,100 picocuries of radon gas per litre of air — were far higher than those in European

Double jeopardy — uranium miners take a cigarette break.

salesman suggested, deadpan, to a prospective customer who had mentioned that she suffered from rheumatism. After 15 minutes of squeezing, she said that she felt no more pain and bought \$50,000 worth of uranium stock. On May 27, 1954, seven million uranium shares changed hands in Salt Lake City, setting a daily record. A commentator noted in the *Salt Lake Tribune*, "It's a giant slot machine with uranium shares instead of bells" (p. 109).

Investors, high on paper profits one day, were brought to earth the next by fraud and bankruptcy. Utah officials resisted regulation by the United States Securities and Exchange Commission, preferring to keep oversight of uranium stocks in local hands, which were more sympathetic than federal authorities might be to venture capital fliers. Anyway, it was said, you couldn't legislate financial morals or protection. Eventually, many Utah brokerage houses were indicted for violations of federal security regulations and a number lost their broker's licences. In 1955, the boom in uranium stocks ended, but the uranium

mines where a large percentage of workers had eventually contracted lung cancer.

No copies of the report were made available to the miners — Holaday and his colleagues had gained access to the mines by tacitly agreeing not to disseminate their findings in a way that might alarm the men down in the shafts. High officials of the AEC declined to publicize it for fear that general knowledge of the risks might jeopardize the production of uranium. Before the report was produced, and also in the years after it, Holaday urged the adoption of various safety measures — notably much-improved ventilation — to reduce the radiation hazards. Some of the larger mines responded with meliorative action, but most of the operators on the Plateau did not. All the while, the AEC insisted that it had no authority to impose safety standards. When the issue came up in 1959, the Commission typically passed the buck to state health agencies, which did virtually nothing, and to the Public Health Service, which had no regulatory leverage and whose only recourse, as Ringholz puts it, was to "implore, exhort,

From *Uranium Frenzy*.

attempt to educate" (pp. 148–150).

By the early 1960s, the miners in Holaday's study cohort were dying of lung cancer at a higher rate than expected on the basis of the incidence of the disease in the general population. In 1963, the widow of one of them, Mrs Eola Garner, started to press a legal case for compensation. In 1967, J.V. Reistrup, a reporter for the *Washington Post*, brought the plight of the miners to national attention and Willard Wirtz, the Secretary of Labor, on the authority of an old statute finally acted to set federal safety standards in the uranium mines. By 1977, when Mrs Garner at last won a favourable settlement from the state of Colorado, conditions in the mines were much safer.

*Uranium Frenzy* is not a probing analysis of high policy, but it is a fine example of high and absorbing journalistic art. It graphically depicts the behaviour and attitudes in the uranium game on the Colorado Plateau, delineating in moving counterpoint the United States govern-

ment's material success against the ill fate of the men who dug the precious ore out of the rock. Ringholz's prose is detached and clear-eyed, understated yet unsparing in its assessments of the winners, the victims, the public health officials who tried to forestall the tragedy that befell the miners — and the bureaucratic postures that prevented them from succeeding. Her book makes utterly plausible the summary of the uranium craze that Stewart Udall, the one-time Secretary of the Interior, supplied her in a letter, in November 1987: "What is most poignant is that the losers were innocent victims — and the Atomic Energy big shots were 'patriots' who lied to protect what they conceived as the 'national interest'" (p. 262). The lies may have taken the form mainly of suppressions and omissions, but they were lies, fatal lies, nonetheless. □

## In his own time

Mark Ridley

**The Non-Darwinian Revolution: Reinterpreting a Historical Myth.** By Peter J. Bowler. *The Johns Hopkins University Press: 1988. Pp.238. \$30.25, £17.50.*

THE Reverend Thomas Malthus, who is well known for his belief that population growth must exceed the food supply, argued also that the resulting food shortage is beneficial for the human race. It raises people out of idleness and torpor. "The necessity of food for the support of life [he wrote] gives rise, probably, to a greater quantity of exertions than any other want, bodily or mental." It is these exertions that have been the motor of human progress — "Had population and food increased in the same ratio, it is probable that man might never have risen from the savage state". Malthus's ideas would develop into the familiar Victorian idea of 'progress through struggle': we desire to better our condition, we strive to do so and (provided the government follows a *laissez faire* policy) progress is the result.

Historians, and biologists, have often described Darwin's theory as an expression of the broader Victorian political economy. Strictly, this has no bearing on whether Darwin was right; but Darwin's critics have always been fond of the analogy, both for the ideological tarnish and the chance of compromising Darwin's originality. Peter Bowler's latest book is most interesting for the thorough, critical look it takes at the historical question.

Bowler has to deal with three argu-

ments. First, that Darwin's theory apparently resembles those of Malthus, and of Herbert Spencer and other Victorian writers; second, that natural selection was simultaneously discovered, at least by Alfred Russel Wallace and perhaps by Patrick Matthew and Edward Blyth, which suggests that the idea was indeed in the air; and finally, that Darwin's theory was rapidly accepted and developed into the influential politics of social Darwinism.

Bowler has objections to all three arguments. For a start, the way that the struggle for existence led to progress was crucially different in the theories of Darwin and of the political economists. For Malthus, and Spencer, the struggle worked as a stimulus to individual action, whereas in Darwin's theory selection takes place on inherited differences between individuals within a population. As Bowler neatly puts it, in Spencer's Lamarckist theory, evolution takes place in individuals, not populations; it lacks what Ernst Mayr calls 'population thinking'.

Wallace's theory may also have differed from Darwin's. In modern population genetic terms, Wallace appears to have been a group selectionist who thought of all selection as 'hard'. He was concerned with selection between "varieties", not individuals, and thought that selection only took place when a variety did not possess an adaptation needed to survive the external environment. Wallace's theory, like Spencer's, lacked Darwin's ideas of intraspecific competition and individual selection.

Finally, Darwin's theory was hardly accepted at all in the late nineteenth, or the early twentieth, centuries. What actually happened was that Darwin persuaded

biologists only about evolutionary change. They then called themselves Darwinians, but were really (what Bowler calls) "pseudo-Darwinians": they believed not in the Darwinian sort of branching, contingent, unplanned evolution, but in evolution through a series of developmental stages from protozoa to human beings. The developmental model of evolution resulted in the recapitulatory, Haeckelian kind of research in embryology, and in the theory of orthogenesis in palaeontology: both of these theories were still teleological, even if the static teleology of pre-Darwinian natural teleology had become the temporal teleology of orthogenesis. Bowler also argues that social Darwinists were inspired by Spencer's Lamarckist and progressive model of evolution, rather than by Darwin. In another chapter he describes a similar tendency in anthropology, as human evolution was considered to proceed through a series of racial stages, from savages to civilized Westerners.

Darwin thus appears as a historically isolated figure. There was no 'Darwinian revolution'. The main stream of Victorian thought started with the natural theologians and idealists, such as Richard Owen, who believed in a more or less atemporal plan of nature. It ran through Chambers, and Spencer, who tried to temporalize the plan, but proved unpersuasive. Darwin, however, was successful. He unintentionally led late-nineteenth-century biologists to accept a temporal, though still teleological, plan of nature, in which evolution proceeds through a series of stages, driven by some process of directed variation. He convinced no one either about his branching and non-progressive theory of evolution, or his materialist mechanism for it.

The 'Darwin industry' has often been criticized for concentrating on Darwin and ignoring his historical context. Bowler himself has some sharp things — not well directed, in my opinion — to say about that industry. *The Non-Darwinian Revolution* is a professional and worthwhile book, which merits reading; it offers a new (at least for the non-specialist reader) interpretation of events about which most people have opinions. I only really disagree with the way Bowler treats his fellow historians, whom he from time to time ignores or caricatures, but this is only a minor defect. Indeed, the industry itself may enjoy the last laugh. If we look past Bowler's various criticisms, and concentrate on his conclusions, he appears to have vindicated those whom he purports to oppose. Bowler has given Darwin his real Victorian context: and ends up justifying those who study Darwin in isolation. □

## Into the fishy business

J. H. S. Blaxter

**The Provident Sea.** By D. H. Cushing. Cambridge University Press: 1988. Pp. 329. £37.50, \$65.

THE history of fisheries demonstrates some of mankind's better individual qualities — the ability to innovate and organize, and ruggedness under harsh conditions — as well as some less-desirable national foibles such as aggression and greed. These human attributes are well brought out in Cushing's book, which shows that fishermen and fishery biologists have some of the better qualities in common!

The history of fishing is dealt with on a wide geographical basis and some fisheries (mainly of the Northern Hemisphere) are described case by case — for example the North Sea herring fishery, the Newfoundland cod and harp seal fisheries, the Pribilof fur seal fishery and the great fisheries for whales. The origins of fisheries research and its increasing sophistication between 1945 and 1965, and from 1965 to the present time, are examined in relation to similar phases in the development of the regulating bodies or institutions concerned.

In prehistoric times, fish were caught by hook and harpoon; nets were already in use in the Neolithic. But a well-documented expansion took place in high-seas fisheries in the Middle Ages when fish caught in the Baltic and North Sea became a major source of employment and wealth, for example for the Hanseatic towns. Soon a high degree of international organization and integration evolved, not only in the fishing itself, but in landing, on-shore processing, transport and marketing.

Certain advances can then be identified, each causing a new leap forward. The first was the invention of on-board curing of herring by the Dutch in the fourteenth century. There followed the introduction of steam tugs for towing sailing vessels in and out of port in the middle 1800s, and then steam engines for propulsion and handling gear on the fishing vessels themselves in the late 1800s. The post-1945 development of stern trawlers, freezing at sea, use of midwater trawls and purse seines, and the deployment of fishing fleets with mother ships and catchers increased the world catch enormously, leading to its probable present asymptote near 80 million tonnes a year.

A large part of the book consists of chapters on the origin of fisheries research in the last century and its progress after the Second World War. The concomitant setting-up of international regulatory bodies closely parallels the development

of research. Clearly, the initiative for research and regulation stemmed from the increasing power and efficacy of the fleets, which began to cause severe depletion of fish stocks, a problem of little importance in the pre-steam days.

As the author points out, at one time nations went to war over their fisheries; now they try to resolve their problems by appraising the scientific evidence. The story of the interplay between fishermen and fishing, and fishery scientists and regulation, is a fascinating mix of ignorance, greed, optimism, political expediency and idealism. Apart from some Scandinavian countries such as Iceland and Norway, where scientists may be held in some esteem, fishery biologists have been treated with suspicion by the fishermen, who have resented the loss of short-term profits and ignored the goal of long-term consistency of catch. The ever-increasing effect of overfishing has recently led to a greater appreciation by fishermen of the need for regulation. Earlier methods of regulation, such as minimum mesh sizes, have of late been supplemented by the imposition of quotas for vessels and total allowable catches for fisheries. Usually the medicine prescribed can easily

be agreed by the scientists on an international basis — even if the politicians find it difficult to allocate the dose to their respective countries.

Cushing does not commend his book to any particular readership. Parts of it are probably too technical for the historian or economist, or too specialized for the undergraduate. Rather, it seems ideal for MSc students on fisheries management courses, or as background reading for marine and fishery biologists as well as civil servants and politicians — throughout the world, fisheries are often now as much a political as a commercial or scientific matter. The author does not refer to the increasing importance of freshwater fisheries and aquaculture (together yielding about 11 million tonnes in 1986), nor does he attempt to forecast the future. Although such additions would have enhanced the value of the book, it already contains an unusual and useful mixture of history, economics and science. It will no doubt find its way into many libraries — not least, I hope, those of certain government departments. □

J. H. S. Blaxter is Deputy Chief Scientific Officer at the Dunstaffnage Marine Laboratory, PO Box 3, Oban, Argyll PA34 4AD, UK.

## The Great Dane

H.B.G. Casimir

**Harmony and Unity: The Life of Niels Bohr.** By Niels Blaedel. Science Tech Publishers, 701 Ridge Street, Madison, Wisconsin: 1988. Pp. 323. \$35. Distributed outside North America by Springer-Verlag, DM98, £32.

NIELS BOHR was one of the greatest physicists of our century. His papers on the spectrum of hydrogen, in which he postulated the existence of stationary states and of quantum jumps, inaugurated the era of the quantum theory of line spectra, led to an understanding of the periodic system of the elements — another notable contribution of Bohr's — and finally to the formulation of quantum mechanics. Bohr did not contribute to the mathematical formalism of the new mechanics, but his doctrine of 'complementarity' played an essential role in clarifying its interpretation. He then turned from atomic to nuclear physics, introducing the notion of highly excited intermediate states in nuclear reactions and explaining many features of uranium fission. Through his writings, and even more through personal discussions, he had an enormous influence on younger physicists.

During the Second World War Bohr escaped from his native Denmark, reaching the United States by way of Sweden and England. He was keenly aware of the

Niels Bohr — an enormous influence on younger physicists.

decisive role nuclear weapons were going to play in international politics, and foresaw with great clarity the threat of a cold war, but his attempts to convince Roosevelt and Churchill that they should come to terms with the Soviet Union at an early date were unsuccessful.

He was certainly a true citizen of the world. But, as one of his biographers, quoted by Blaedel, remarks, he was so deeply rooted in Danish culture and the Danish way of thinking and feeling that, if he had grown up in some other country, he would not have been Niels Bohr. He was also the head of a wonderful family. ▶

There is no lack of published material about Bohr. The edition of his collected papers also contains many biographical details, letters and so on, and there have been numerous obituaries and at least two commemorative volumes. In this book, a translation and slight revision of the Danish edition of 1985, Blaedel has addressed himself to the task of writing a full-length biography that covers all facets of his subject and that emphasizes that they form part of one harmonious unity. I think that on the whole he has succeeded remarkably well. He gives an accurate picture of the man theorists of my generation both admired and loved. And not only of the physicist: Bohr's relations with his family and in particular with his wife, an admirable woman, are drawn with sympathy and understanding.

Blaedel's sketch of the atmosphere at Bohr's institute in Copenhagen, where work was combined with — often somewhat childish — playfulness, especially in the late 1920s and early 1930s, is true to life; it will raise nostalgic memories among those who, like myself, experienced it. I am not so sure about the physics, however. The essential subjects are included and I have not spotted obvious errors, but I wonder whether Blaedel's account of the discussions between Bohr and Einstein — to give one example — will be comprehensible to non-physicists. Here, though, is a book to be read as a biography and not as an introduction to modern physics.

The translation from the Danish is in general satisfactory, although I noticed one or two slips. A few errors in the original have been corrected, and here and there short explanations have been added to help readers who are unfamiliar with Danish geography and Danish history and literature. The book is richly illustrated; although the quality of reproduction is not as high as that of the rather sumptuous original (which also contains a few colour plates), it is perfectly adequate.

Some readers may regret that the book is more a eulogy than a critical appraisal — that Blaedel does not mention any scientific shortcomings or any less desirable human traits. So be it. Personally I think he has produced a fitting tribute to a great scientist and a noble man. □

*H.B.G. Casimir, De Zegge 7, 5591 TT Heeze, The Netherlands, studied theoretical physics at Leiden, Copenhagen and Zürich, and from 1946 to 1972 was Research Director of the Philips Company at Eindhoven.*

#### New in Britain

Just published by Unwin Hyman, price £11.95, is *"What Do You Care What Other People Think"* by Richard Feynman as told to Ralph Leighton. The book, which was published last autumn in the United States by W.W. Norton and reviewed in *Nature* on 3 November, tells largely of Feynman's productively unconventional work on the inquiry into the failure of the Challenger space shuttle.

## Wholesome ideals

*P. W. Atkins*

**Science, Order and Creativity.** By David Bohm and F. David Peat. *Routledge: 1988. Pp.280. Pbk £5.95.*

THE world will be much nicer once 'creativity' has been liberated from its present tomb, the walls of which are built from the attitudes of conventional science. This is the message that David Bohm and F. David Peat urge on us in this somewhat bizarre and certainly uneven book that has grown out of conversations that the two have had together over the years. I began to read with high hopes. But although some of the early passages show interesting insights, in general my dislike grew with the page numbers.

The book is pervaded on the one hand by a schoolboy naïveté ("How does science intend to end the danger of mutual annihilation that exists in the world?") and on the other by a pessimism about the potential of and the attitudes currently struck by conventional science. Before considering purchasing it, those who are sensitive to these things will want to know that both Sir Fred Hoyle and Rupert Sheldrake are mentioned without disapproval.

To be fair, I must allow the authors to speak for themselves, for I fear I may be one of those at whom is directed the accusation of being a prisoner of conventional science, and therefore may be over-tender to its message. The argument begins with an attempt to disarm criticism of what is to come by considering the role of communication in creative perception, and by identifying how communication may break down at the dawn of revolutions in science and at what the authors so fervently long for, the sunrise of a new paradigm. Quantum theory is in this context a paradigm of paradigms, and something of the wars of interpretation is presented here. Rather inappropriately, though, Bohm takes the opportunity to present a moderately lengthy account of his 'causal interpretation', for which he needs the burden of a new potential (the quantum potential, essentially  $\nabla^2\psi^2/\psi^2$ ). The advantage of his formalism appears to be that it does not require a break with classically established concepts; here, however, the authors have tripped over their own feet, for a more relaxed view of quantum theory would lead us to believe that we must unburden ourselves of the expectation of the farmyard and not cling to classical concepts.

Built on these foundations, such as they are, is an account of what is meant by order, its classification and (an essential feature of what is to come) its unfolding.

The authors deal properly with the change in our perception of the concept that has been stimulated by developments in fractals and determinate chaos. To do so, they distinguish between 'constitutive order' (the actual order expressed in the physical constitution of the entity, as in the material hexagons of a beehive) and 'descriptive order' (the order that stems from an abstraction, as in the motion of an object through a field of coordinates). They argue that actual order (whatever that is) lies between these two extremes, and thus alight on what is for them the comforting view that order is a cycle of activity that involves both. It is in this chapter that the generally 'Eastern' flavour of the book begins to be explicit for the first time.

The authors are desperate to eliminate the fragmentation of conventional science and thus to impress upon us the essential 'wholeness' that is crucial to comprehension and human progress. Hence order, of various degrees, kinds and hierarchies, is essential to their argument. Thus they go on to distinguish 'generative order' from 'implicate order'. The former is an "inward order out of which the manifest form of things can emerge creatively". The rule for generating fractals would be an example. The latter is a particular kind of generative order that, I must confess, leaves me confused, for to comprehend it we must somehow understand that "the basic movement of enfoldment and unfoldment is thus a dual one in which there is ultimately no separation between enfoldment and the unfoldment". There is, of course, a superimplicate order too.

In the tacit infrastructure of consciousness, the authors claim, there are rigid ideas that restrict creativity. (I suspect, on the contrary, that they constitute a ladder to comprehension.) These ideas operate close to the source of the generative order and, as well as restricting creativity, imply "the presence of an energy that is directed toward general destructiveness". Whatever that means, I feel that it is the manifestation of the authors' pessimism, and more truly the spur of their writings than the overt joy of enlarged comprehension that they claim to be the book's impetus.

Bohm and Peat urge on us the "key importance of liberating creativity" if human life is to have a worthwhile kind of survival. And how do we escape from our prison? We need to de-fragment science, attain wholeness, comprehend levels of order, give up the hope of true and total comprehension, and, perhaps most important of all, "clear up" the sociocultural dimension. It really is as easy as that. □

*P.W. Atkins is in the Physical Chemistry Laboratory, University of Oxford, and is a Fellow of Lincoln College, Oxford OX1 3DR, UK.*

# VCH Selection on Spectroscopy

## Carbon-13 NMR Spectroscopy

### High-Resolution Methods and Applications in Organic Chemistry and Biochemistry

Third, completely revised edition  
by E. Breitmaier and W. Voelter

1987. XVI, 515 pages with 129 figures and 158 tables. Hardcover.  
£ 98.95.  
ISBN 3-527-26466-3

## Mass Spectrometry/ Mass Spectrometry Techniques and Applications of Tandem Mass Spectrometry

by K. L. Busch, G. L. Glish and  
S. A. McLuckey

1988. 350 pages, 40 figures and 14 tables. Hardcover.  
£ 51.00.  
ISBN 3-527-26785-9

## Two-Dimensional NMR Spectroscopy Applications for Chemists and Biochemists

edited by W. R. Croasmun and R. M. K. Carlson

1987. 623 pages with 186 figures and 33 tables. Hardcover.  
£ 72.00.  
ISBN 3-527-26528-7\*

## High Resolution NMR Spectroscopy of Synthetic Polymers in Bulk

edited by R. A. Komoroski

1986. XI, 379 pages with 168 figures and 51 tables. Hardcover.  
£ 79.00.  
ISBN 3-527-26464-7\*

## Spectroscopy with Polarized Light Solute Alignment by Photo- selection, in Liquid Crystals, Polymers, and Membranes

by J. Michl and E. W. Thulstrup

Editors: **SIDNEY F A KETTLE**, *School of Chemical Sciences, University of East Anglia, Norwich NR4 7TJ, UK* and **JEFFREY I STEINFELD**, *Department of Chemistry, Massachusetts Institute of Technology, Cambridge, MA 02139, USA*

This international journal is intended for the rapid publication of original work dealing with molecular spectroscopy, and its application in chemical problems. Subject areas include infrared, visible, ultraviolet, Raman, microwave, and photoelectron spectroscopy, nuclear magnetic and electric spin resonance, optical rotatory dispersion and magnetic circular dichroism, and neutron and light scattering. In addition to fundamental papers on molecular structure and interactions, papers dealing with applications in areas such as qualitative and quantitative analysis, surface spectroscopy, non-linear optics, laser photochemistry, aeronomy and extra-terrestrial spectroscopy, instrumentation, and biochemistry are also published.

# APPLIED AND THEORETICAL ELECTROPHORESIS

An official publication of the International Electrophoresis Society

Editor-in-Chief: Carl R. Merrill, Rockville, Maryland USA

## CONTENTS OF ISSUE 1 (Fall 1988)

Computerized classification of two-dimensional gel electrophoretograms by correspondence analysis and ascendant hierarchical clustering: **Pun, Hochstrasser, Appel, Funk, Villars-Augsburger & Pellegrini**

Improved separation of multi-locus hypervariable DNA restriction fragments by field inversion gel electrophoresis and fragment detection using a biotinylated probe: **Fowler, Skinner, Burgoyne & McInnes**

Rapid scanning thermal lens/laser transmission densitometer: **Peck, Demana & Morris**

A zone electrophoretic-isoelectric focusing study on the inactivation of human alpha 1-antitrypsin by elastase: **Baumstark**

Mixture decomposition applied to the analysis of two-dimensional electrophoretic separation of protein samples: **Taylor & Giometti**

Fingerprinting of proteins cleaved in solution by cyanogen bromide: **Skopp & Lane**

An equation for DNA electrophoretic mobility in agarose gels: **Willis, Willis & Holmquist**

HDL particle associated proteins in plasma and cerebrospinal fluid: identification and partial sequencing: **Hochstrasser, James, Martin, Harrington, Hochstrasser, Pometta & Merrill**

The effects of field inversion electrophoresis on small DNA fragment mobility and its relevance to DNA polymorphism research: **Gejman, Sitaram, Wang-Ting Hsieh, Gelernter & Gershon**

'Catalysts' for polyacrylamide gel polymerization and detection of proteins by silver staining: **Hochstrasser & Merrill**

Submicrogram quantities of unstained proteins are visualized on polyvinylidene difluoride membranes by transillumination: **Reig & Klein**

Thermally reversible gels in electrophoresis I: matrix characterization: **Righetti, Snyder**

The mechanism of DNA's fractionation during pulsed-field agarose gel electrophoresis: a hypothesis: **Serwer**

## M-Scan

Mass Spectrometry Consultants and Analysts

### Biopolymer Sequencing

World leaders in the application  
of new Mass Spectrometric  
techniques including High Field  
Fast Atom Bombardment to the  
solution of PROTEIN and  
CARBOHYDRATE research  
problems.

### Structure Analysis Service

- Analysis of recombinant DNA protein and glycoprotein products.
- Identification of post-translational modifications including sites of glycosylation, sulphonation etc.
- Protein sequence and di-sulphide bridge assignment.
- Confirmation of identity of synthetic peptides.
- Identification of N- and C- terminal blocking groups and "ragged-ends".
- Structure of oligosaccharides and glycoconjugates.

### FAB-MS Training Course : 17/19th April 1989

- Sequencing using MS methods in conjunction with classical techniques.
- FAB Mapping methods for analysis of natural and recombinant proteins, carbohydrates and nucleotides.

## GUIDE TO AUTHORS

Please follow these guidelines so that your manuscript may be handled expeditiously.

*Nature* is an international journal covering all the sciences. Contributors should therefore bear in mind those readers for whom English is a second language and those who work in other fields. Please write clearly and simply, avoiding unnecessary technical terminology. *Nature's* staff will edit manuscripts to those ends if necessary. Contributors should check their proofs carefully. Because of the competition for space, many of the papers submitted for publication cannot be accepted. For this reason, and because brevity is a great assistance to readers, papers should be as brief as is consistent with intelligibility. Please note that one printed page of *Nature*, without diagrams or other interruptions of the text, has fewer than 1,300 words.

### CATEGORIES OF PAPER

**Review Articles** survey recent developments in a field. Most are commissioned, but suggestions are welcome in the form of a one-page synopsis addressed to the Reviews Coordinator. Length is negotiable in advance but must not exceed six pages of *Nature*.  
**Articles** are research reports whose conclusions are of general interest and which are sufficiently rounded to be a substantial advance in understanding. They should not have more than 3,000 words of text or more than six display items (figures and tables) and should not occupy more than five pages of *Nature*.

Articles should be accompanied by a heading of 50–80 words written to advertise their contents in general terms, to which editors will pay particular attention. A heading (printed in *italic type*) is not an abstract and should not usually contain numbers or measurements. The study should be introduced in more detail in the first two or three paragraphs, which should also briefly summarize its results and implications.

Articles may contain a few subheadings of two or three words. The meaning of the text should not depend on the subheadings, whose function is to break up the text and to point to what follows. There should be fewer than 50 references.

**Letters to *Nature*** are short reports of outstanding novel findings whose implications are general and important enough to be of interest to those outside the field. Letters should not have more than 1,000 words of text or more than four display items and should not occupy more than two pages of *Nature*. The first paragraph should describe, in not more than 150 words, the origins and chief conclusions of the study. Letters should not have subheadings or more than 30 references.

**Commentary** articles deal with issues in, or arising from, research that are also of interest to readers outside research. Some are commissioned, most are unsolicited. They are normally between one and four pages of *Nature* in length.

**News and Views** articles are intended to inform non-specialist readers about a recently published advance. Suggestions should be made to the News and Views Editor. Illustrations are welcome. Proposals for meeting reports should be agreed in advance.

**Scientific Correspondence** is for the discussion of scientific matters, including contributions published in *Nature*. Priority is given to contributions of less than 500 words and five references. Figures are welcome.

**Submission.** All manuscripts may be submitted to either London or Washington. They should not be addressed to editors by name. Manuscripts or proofs sent by air courier to London should be declared as "manuscripts" and "value \$5" to prevent the imposition of import duty and value-added tax (VAT).

### GENERAL

All contributions submitted for publication in *Nature* should conform with these rules.

**Manuscripts** should be typed, double-spaced, with a good-quality printer, on one side of the paper only. Four copies are required, each accompanied by lettered artwork. Four copies of half-tones should be included. Reference lists, figure legends and so on should be on separate sheets, all of which should be double-spaced and numbered. Copies of relevant manuscripts in press or submitted for publication elsewhere should be included, clearly marked as such. Revised and resubmitted manuscripts should also be clearly marked as such and labelled with their reference numbers.

**Titles** should say what the paper is about with the minimum of technical terminology and in fewer than 80 characters. Authors should avoid active verbs, numerical values, abbreviations and punctuation and should include one or two key words for indexing purposes.

**Artwork** should be marked individually and clearly with the author's name, figure number and, when known, manuscript reference number. Original artwork should be unlettered. Ideally, no figure should be larger than 28 by 22 cm. Figures with several parts are permitted only if the parts are closely related, either experimentally or logically. Suggestions for cover illustrations, with captions, are welcome. Original artwork (and one copy of the manuscript) will be returned when a manuscript cannot be published.

**Colour Artwork.** A charge of £500 a page is made for 4-colour figures. Inability to meet these costs will not prevent the publication of essential colour figures if the circumstances are explained.

**Figure legends** must not exceed 300 words and ideally should be much shorter, and should use telegraphic form wherever possible. The figure should be described first, then, briefly, the method. Reference to a method described elsewhere is preferable to a full description. Methods should not be described in detail in the text.

**References** should be numbered sequentially as they appear in the text, followed by those in tables and finally those in the figure legends. Reference numbers apply only to papers published or in the press, and a different number should be given to each paper cited. All other forms of reference (including unrefereed abstracts) should be included in the text as personal communication, manuscript in preparation or preprint (with number and institution where appropriate). Text should not be included in the reference list. References should be abbreviated according to the *World List of Scientific Periodicals* (fourth edition, Butterworth, London, 1963–65). The first and last page numbers should be cited. Reference to books should clearly indicate the publisher and the date and place of publication.

**Abbreviations, symbols, units and Greek letters** should be identified the first time they are used. Acronyms should be avoided as much as possible and, when used, defined. Editors will shorten words if necessary. In case of doubt, SI units should be used.

**Footnotes** should not be used except for changed addresses or to identify the corresponding author if different from the first named.

**Acknowledgements** should be brief. Grant numbers and contribution numbers are not allowed.

# Geochemical implications of the formation of the Moon by a single giant impact

Horton E. Newsom & Stuart Ross Taylor

The origin of the Moon by a single massive impact of a body slightly larger than Mars with the Earth can explain the angular momentum, orbital characteristics and unique nature of the Earth–Moon system. The density and chemical differences between the Earth and the Moon are accounted for by deriving the Moon from the mantle of the impactor. A cosmochemically plausible impactor can be formed in the region of the inner Solar System, lending support to the impact hypothesis.

THE Earth–Moon system has several unique features. None of the other terrestrial planets possesses a comparable moon—the tiny martian moons, Phobos and Deimos, are probably captured asteroids. The angular momentum of the Earth–Moon pair is anomalously high compared with that of the other inner planets, and the inclination of the lunar orbit is strange. The Moon has a high mass (1/81.3) relative to the Earth when compared with the satellites of the giant planets, but its bulk density ( $3.34 \text{ g cm}^{-3}$ ) is much lower than that of the Earth or the other inner planets, probably because of a low metallic iron content.

The chemical composition of the Moon, revealed by the samples from the Apollo and Luna missions, is also unusual. The Moon is bone dry, is strongly depleted in volatile elements such as potassium, lead and bismuth, and probably enriched in refractory elements such as calcium, aluminium, titanium and uranium (see box). In bulk, it contains ~50% more FeO than the upper mantle of the Earth.

In view of this diverse set of properties, it is perhaps not surprising that theories for the origin of the Moon have generally been unsatisfactory. Only recently has a model been proposed that is widely considered to be acceptable: the single impact hypothesis. This theory proposes that during the final stages of the accretion of the terrestrial planets, a body somewhat larger than Mars collided with the Earth and spun out a disk of material from which the Moon formed. Here we will review the evidence for this theory and show how it can account for the unusual chemical composition of the Moon.

## Older hypotheses

Including the single impact theory, there are five main classes of hypothesis for the origin of the Moon, although elements of some appear in others. The four older hypotheses fail to explain the unique nature of the Moon because they do not account for the lunar orbit or the high angular momentum of the Earth–Moon system, and because they entail processes that might have been common in the early Solar System, implying that similar satellites should accompany all the inner planets.

Capture of an already formed Moon from an independent orbit is improbable on dynamical grounds<sup>1</sup> and does not explain

the compositional peculiarities, as the Moon would be expected to be an example of a common early Solar System object<sup>2</sup>.

Formation of the Earth–Moon system as a double planet immediately stumbles on the difficulties of density and composition. To overcome the density problem, co-accretion was proposed<sup>3</sup>; in this model the Moon formed from a ring of low-density silicate debris shed from the mantles of incoming differentiated planetesimals, whose iron cores survived to accrete with the Earth. Although attractive, this scenario is improbable<sup>1</sup> because the breakup of planetesimals is unlikely to occur and it is difficult to achieve the required angular momentum<sup>4</sup>. In a similar model for co-accretion and evolution of a circum-terrestrial disk<sup>5,6</sup>, it has been shown that the angular momentum is attained only in very special conditions.

Fission hypotheses, which derive the Moon from the terrestrial mantle<sup>7</sup>, have been popular because they explain a low-density, metal-poor Moon, but they had to be abandoned after lunar samples showed significant differences in chemical composition between the Moon and the Earth's mantle<sup>8</sup>. A modification of this hypothesis<sup>9,10</sup> suggests that mantle material was thrown into orbit by many small impacts. Apart from the inherent chemical difficulties, it is exceedingly difficult to obtain the required angular momentum this way<sup>1,11</sup>. A further elaboration of this proposal, involving capture of objects in heliocentric orbits by an extended Earth atmosphere<sup>9</sup>, is not supported by existing evidence<sup>8,12,13</sup>, and this model also fails to account for the unique status of the Moon.

## Single impact hypothesis

Formation of the Moon as the result of a single collision of a large body with the early Earth resolves many of these problems. The theory was first proposed to account for the anomalous angular momentum<sup>14</sup>, but also provides an explanation for the other properties and has now become widely accepted<sup>15</sup>.

In assessing the single impact theory, one must first ask whether a suitably large body existed in the early Solar System (before 4.4 Gyr). One scheme for the origin of the terrestrial planets<sup>12</sup>, in which they are accreted from a suite of rocky planetesimals over a period of  $10^7$ – $10^8$  yr, leads to a hierarchy of large bodies. In the final stages of accretion, perhaps 100 objects of lunar mass, 10 of the mass of Mercury and a few Mars-sized bodies populate the inner Solar System<sup>12</sup> before being swept up into the four inner planets.

There is considerable evidence for this scheme. Craters and ringed basins over 1,000 km in diameter on the Moon, Mercury, Mars and the satellites of the outer planets<sup>16</sup> attest to an early (>3.8 Gyr) intense bombardment by a large range of objects. The axes of nearly all the planets are significantly tilted relative to the plane of the ecliptic; the most dramatic example is Uranus, which is lying on its side, probably as a result of a collision with an Earth-sized object. The slow backward rotation of Venus, unique in the Solar System, is most rationally attributed to a

### Classification of the chemical elements

To describe the behaviour of the elements in the solar nebula, cosmochemists divide them according to their volatility (examples in parentheses): 'gaseous' (hydrogen, carbon, nitrogen, oxygen and the noble gases), 'very volatile' (bismuth, thallium), 'volatile' (rubidium, caesium), 'moderately volatile' (potassium, manganese), 'moderately refractory' (vanadium, europium), 'refractory' (calcium, aluminium, uranium, lanthanum) and 'super-refractory' (zirconium, scandium). The terms lithophile, chalcophile and siderophile describe those elements that preferentially enter silicate, sulphide or metal phases, respectively. This classification is based primarily on the distribution of elements in these phases in meteorites.

late collision with a massive, perhaps Mars-sized object; with a different mass, angle and velocity, the impact might have provided Venus with its own moon.

Further evidence comes from the varied compositions of the planets; accretion from a dusty nebula, rather than from planetesimals, might be expected to produce rather uniform planetary compositions. Meteorites, too, come from many distinct parent bodies and are commonly mixtures of several components, or fragments of larger bodies. The asteroid belt, arrested at an early stage of planetary development, probably owing to the gravitational influence of the gaseous giant Jupiter, preserves a wide size range of objects (the largest, 1 Ceres, is 1,020 km in diameter). Finally, Mercury's anomalously high density and large iron core are most simply explained by removal of most of its silicate mantle by collision with a large body<sup>17</sup>; alternative schemes involving high-temperature evaporation of silicates remove unrealistic amounts of material<sup>18</sup> and do not account for the presence of sodium ions, probably sputtered from the surface, in Mercury's tenuous atmosphere<sup>19</sup>.

### Impact dynamics

Studies of the single impact hypothesis<sup>20-26</sup> have led to the following sequence of events (see Fig. 1). When the Earth had attained nearly its present size, it suffered a grazing impact, at about  $5 \text{ km s}^{-1}$ , with an object of  $\sim 0.14$  Earth masses, somewhat larger than Mars<sup>20,21</sup>. Both this body and the Earth are assumed to have differentiated into a metallic core and silicate mantle. The collision disrupts the impactor, much of which goes into orbit around the Earth, accelerated by the gravitational torques arising from the asymmetrical shape of the Earth following the impact<sup>20,21</sup>, and by expanding gases from the vaporized part of the impactor<sup>14,23</sup>. While the impactor's mantle is being accelerated away from the Earth, its metallic core separates from the mantle, decelerates, and accretes to the Earth in about four hours<sup>22</sup>.

The material that achieves orbit is initially present as a disk partly inside and partly outside the Roche limit ( $\sim 2.9$  Earth radii)<sup>22,25,26</sup>. Some of the material inside the Roche limit ends up outside through transfer of angular momentum. The material may immediately coalesce to form a totally molten Moon, or break up into several moonlets which then accrete to form a partly molten Moon<sup>26</sup>. Geochemical studies indicate that at least half the Moon was molten shortly after accretion, with the feldspathic highland crust crystallizing from this 'magma ocean'<sup>27</sup>; in general, a partly rather than fully molten Moon seems most consistent with geochemical and geophysical constraints<sup>26</sup>.

### Lunar composition

Only a small amount of material from the Earth's mantle (probably less than 16%<sup>20,22</sup>) eventually ends up in the Moon. This is supported<sup>8</sup> by the low FeO content of the terrestrial mantle (8%) as compared with the Moon (13%), which would otherwise require that the FeO content of the impactor mantle be unreasonably large ( $>13\%$ )<sup>28</sup>. A Moon formed from 85% impactor mantle and 15% terrestrial mantle requires an impactor mantle with 14% FeO.

Additional evidence that there is relatively little terrestrial mantle material in the Moon comes from the isotopic composition of potassium<sup>29</sup>. Because the Moon is depleted in volatile elements relative to the Earth's mantle, the mass fractionation due to volatile loss should have left the Moon enriched in the heavier potassium isotopes. The fact that the isotopic composition of potassium in lunar feldspars is close to that of CI carbonaceous chondrites, considered to be typical of the solar nebula<sup>29</sup>, limits the contribution from the Earth's mantle to  $<20\%$ .

Relative to chondritic abundances (see Fig. 2 legend for a discussion of the use of carbonaceous chondrites as 'benchmarks'), the Moon and the Earth's mantle show similar depletion

patterns of vanadium, chromium and manganese<sup>9,30</sup>. These contrast with the more chondrite-like abundances inferred for the parent bodies of the eucrite and shergottite meteorites, and are considered by some<sup>9,10</sup> to support an origin of the Moon from the Earth's mantle. But the depletion of Mn relative to V and Cr in the Earth and the Moon is also consistent with volatility having been the primary control on the abundance pattern<sup>31,32</sup>. New experiments on partitioning of these elements between sulphur-rich metallic liquid and silicate melt<sup>31,32</sup>, confirming earlier work on partitioning between pure iron metal and silicate melt<sup>33,34</sup>, as well as data for Cr and Mn in natural metal-silicate rocks from Disko Island<sup>35</sup>, show that V and Cr are more highly siderophile (literally, 'iron-loving'; see box) than Mn. Thus, had these elements been depleted by core formation in the Earth, we would see a greater depletion of V and Cr compared to Mn, contrary to observation. Their depletion in the Earth's mantle, therefore, cannot be ascribed to unique terrestrial processes involving formation of the Earth's core<sup>9,36</sup>, and similar depletions of V, Cr and Mn in the Earth and Moon do not require that the Moon formed primarily from terrestrial mantle material.

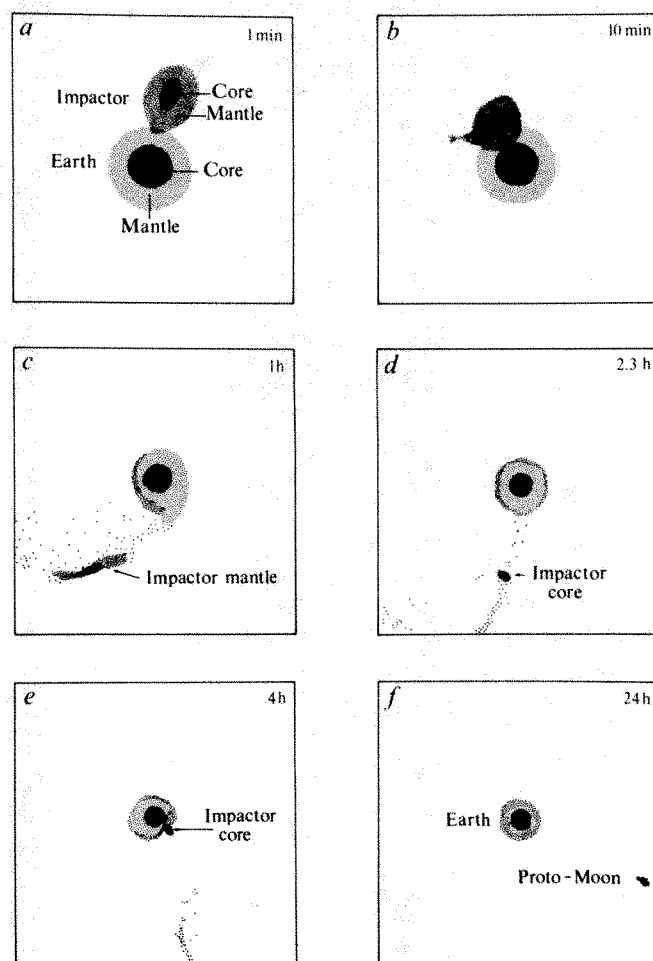

FIG. 1 Computer simulation<sup>20-22</sup> of the formation of the Moon by a giant impact. This reconstruction shows the events following the oblique collision with the Earth of an object of 0.14 Earth masses (slightly larger than Mars) at a velocity of  $5 \text{ km s}^{-1}$ . Both the Earth and the impactor have already differentiated into a metallic core and silicate mantle. The time elapsed since impact is given in each box. Following the collision (a, b), the impactor spreads out in space (c), but the debris clumps together through gravitational attraction. The iron core of the impactor separates from the silicate mantle (d) and accretes to the Earth (e) about four hours after the initial encounter. Nearly 24 hours later (f), a silicate lump of about lunar mass is in orbit around the Earth. This material is principally derived from the silicate mantle of the impactor. Courtesy of A. G. W. Cameron and W. Benz.

## Constraints on impactor composition

What can be deduced about the composition of the impacting body? We will first consider the constraints on the lithophile and volatile element composition of the impactor, and then use the siderophile element depletion patterns in the Earth and Moon to derive the siderophile abundances in the impactor's mantle and the size and composition of the impactor's core. We assume<sup>20-22</sup> that the impactor was 0.14 Earth masses, and was differentiated into a metallic core and silicate mantle. We also assume that it formed in the same part of the solar nebula as the Earth (between Venus and Mars), to account for the low relative impact velocity ( $5 \text{ km s}^{-1}$ ; ref. 23) and the similarity in oxygen isotopes between Earth and Moon. Although there was probably much mixing of planetesimals during their formation, the terrestrial planets retain some memory of having accreted

FIG. 2 Depletion of siderophile elements in the Earth (○) and Moon (●)<sup>42,51</sup>, plotted in order of metal/silicate partition coefficient,  $D^{M/S}$ . The dividing line between moderately and highly siderophile behaviour is taken to be  $D^{M/S} = 10,000$ , meaning that the element is partitioned into the metallic phase with a concentration ratio (metal:silicate) of 10,000:1. The depletions are normalized to abundances in CI chondrites relative to aluminium, because the non-siderophile refractory elements are enriched in the Earth and Moon. The greater depletion of gallium and germanium in the Moon relative to elements with similar siderophile behaviour is probably due to their volatility. Elemental abundances in Solar System objects are usually expressed relative to those in the primitive, volatile-rich meteorites known as CI chondrites. For the non-gaseous elements, these meteorites give the best estimate of the composition of the Sun, and thus of the primitive solar nebula from which the planets formed<sup>56</sup>. Primitive material, unchanged since the formation of the solar nebula, would have flat or 'chondritic' patterns; conversely, any deviation from chondritic abundances (or relative abundances) provides information about an object's chemical history.

from relatively narrow ( $<1 \text{ AU}$ ) feeding zones, a notion supported by the zoned compositional structure of the asteroid belt<sup>37</sup>. **Lithophile and volatile elements.** The constraints imposed by these elements on lunar origins and the single impact hypothesis are only briefly summarized here; for more details, see ref. 8. The impact was sufficiently energetic to vaporize much of the material that went to make up the Moon, explaining such unique features as the bone-dry nature of the Moon and the extreme depletion of very volatile elements. Bismuth and thallium, for example, are depleted by factors of  $\sim 200$  relative to cosmic abundances. Elements that are volatile at temperatures above  $\sim 1,100 \text{ K}$  (such as europium and ytterbium) do not appear to be depleted in the Moon<sup>8</sup>, setting an upper limit on the temperature experienced by proto-lunar material.

If the impactor formed in the region of the terrestrial planets, then it must have been somewhat depleted in volatile elements, as there was an earlier, if less dramatic, depletion of these elements in the inner solar nebula. This is shown by the low volatile/refractory element ratios (for example,  $\text{K/U} = (1-2) \times 10^4$ ) in the Earth, Venus and Mars, compared with initial solar nebula values of  $6 \times 10^4$ .

This depletion event must have occurred very soon after the formation of the Solar System ( $T_0 = 4.56 \text{ Gyr}$ ), as shown by the low initial  $^{87}\text{Sr}/^{86}\text{Sr}$  ratios in meteorites<sup>38,39</sup>, which indicate a very early separation of volatile rubidium from refractory strontium. Also, the lunar initial  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio is close to that of the basaltic achondrites—meteorites which formed as igneous rocks 4.54 Gyr ago<sup>38,39</sup>; thus, lunar  $^{87}\text{Sr}$  must have evolved in a low-Rb/Sr environment from times close to  $T_0$ .

Accordingly, the Rb/Sr ratio was probably lower than chondritic in the lunar precursor material. As the Earth, the Moon and the CO, CM and CV carbonaceous chondrites display similar V-Cr-Mn patterns (see above), this widespread volatility-related depletion may have been caused by early volatile depletion in the nebula, rather than the giant impact. It seems safe to conclude that the impactor mantle was not composed of material with the composition of CI chondrites, but had undergone a volatile depletion similar to that seen elsewhere in the inner Solar System<sup>8,37</sup>, and thus had Rb/Sr ratios, V-Cr-Mn patterns and K/U ratios similar to those of the inner planets; additional potassium, other volatile elements and water were lost in the collision. The physics of volatile depletion during lunar formation needs further study<sup>25</sup>.

The bulk Moon is probably enriched in refractory elements (such as Al, Ti, Ca and U) by a factor of 1.5 compared with the terrestrial mantle, or about 2.5 times the primitive abundances in CI meteorites. The geochemical arguments for this<sup>8</sup> have been buttressed by geophysical studies, which support a high-alumina Moon<sup>40</sup>. The most recent refinement of the geophysical data<sup>41</sup> concludes that "only in the case of extreme assumptions can critical aspects of bulk lunar composition be demonstrated to be equivalent to the present-day terrestrial mantle: specifically the Moon has an  $\text{Mg}\# [= \text{Mg}/(\text{Mg} + \text{Fe})]$  that is too low and an alumina abundance that is too high".

Whether the mantle of the impactor was enriched in refractory elements is less certain; alternatively, fractional condensation from a vapour phase could have enriched the Moon in alumina, uranium and the other refractory elements<sup>8</sup>. But such a process might alter isotopic ratios, and no such effects have been observed in the potassium isotopes<sup>29</sup>. We conclude that the impactor was probably enriched in refractory elements, noting that the Earth is enriched over CI abundances by a factor of 1.5. This raises broad questions about the relative compositions of the terrestrial planets, selective accretion from already differentiated planetesimals, and the effects of massive collisions that remain for future research.

**Siderophile elements.** The depletion patterns of siderophile elements in the Earth and Moon (Fig. 2) provide constraints on their abundance in the mantle of the impactor and on the size of the impactor's core. Two important characteristics of the

siderophile abundances in the Earth's upper mantle are that the highly siderophile elements (such as rhenium and iridium) seem to be uniformly distributed throughout the upper mantle, and have chondritic relative abundances (Fig. 2). These facts are often attributed to accretion of a late (post-core-formation) veneer of meteoritic material to the terrestrial upper mantle<sup>45</sup>, because the siderophile element concentrations are too high to have been in equilibrium with a metallic core.

FIG. 3 Schematic siderophile element depletion patterns for the Earth and Moon, resulting from different siderophile depletion patterns in the impactor mantle. *a*, An impactor resembling a chondritic meteorite, with no segregation into metallic core and silicate mantle. *b*, An impactor mantle with a siderophile element pattern similar to that of the Earth's mantle, without the 'late veneer' of highly siderophile elements. *c*, An impactor with a siderophile element depletion pattern similar to that of the lunar mantle.

The lunar siderophile pattern, by contrast, shows a relatively uniform decrease in abundance (relative to chondrites) of the refractory siderophile elements as a function of their siderophile nature. (Elements such as gallium and phosphorus may also be depleted owing to their volatility.) This depletion pattern is quantitatively consistent with equilibrium between the lunar silicates and Fe-rich metal at low degrees of partial melting<sup>42</sup>, presumably during core formation. (The existence of a lunar core of 350–500 km radius, although not conclusively proven, is consistent with many geophysical data, including the Moon's moment of inertia coefficient<sup>43</sup>, electrical conductivity, and the latest assessment of lunar palaeomagnetism, which seems to require a dynamo in an electrically conducting core between ~4 and 3.5 Gyr ago<sup>44</sup>.) Only the least siderophile elements, such as tungsten and cobalt, are similarly depleted in the Earth and Moon.

The conclusion that core formation can explain the lunar siderophile abundances depends on the lunar core having a relatively low nickel content (<10 wt%<sup>42</sup>). A nickel-rich core would be less efficient at scavenging siderophiles from the silicate phase; thus, if the lunar core were in fact to contain 41 wt% Ni, as has recently been suggested<sup>46</sup>, the Moon's siderophile depletion would have to be explained by its formation largely out of material from the Earth's (already depleted) mantle. We do not feel that this conclusion is required, however, because the figure of 41% was derived from the Ni abundance in Apollo 15 green glass, assuming<sup>46</sup> that this glass represents a liquid from the primitive lunar mantle. In fact, the chemistry of the glass—notably its depletion in europium and strontium, characteristic of other lunar mare basalt samples<sup>27</sup>—indicates that its source region was formed by crystallization from the lunar magma ocean. If this magma ocean was in direct equilibrium with the lunar core, then the Ni content of the green glass would indeed reflect that of the lunar core. This is unlikely, however, because the metal separation would have occurred at some moderate degree of partial melting, whereas the magma ocean probably represents a high degree of melting of the lunar mantle. Assuming that a large proportion of the Moon (or precursor planet) experienced metal segregation at 10% partial melting, following which the silicates were partially or completely melted to form a magma ocean, the nickel content of the metal in the lunar core could range from 10 to 27 wt%.

An additional argument against Ni-rich metal in equilibrium with lunar silicates comes from the very reduced oxidation state of the Moon, which is characterized by a total lack of ferric iron. Lunar basalts crystallized at oxygen fugacities four to five orders of magnitude lower than those of terrestrial basalts at equivalent temperatures<sup>47</sup>. If lunar silicates had equilibrated with Ni-rich metal, lunar oxygen fugacities would be much higher.

The lunar siderophile element pattern allows four possibilities for the siderophile abundances in the impactor, the implications of which are discussed next. The second and third cases seem most plausible.

**An undifferentiated impactor.** The least likely possibility is that the impactor had chondritic abundances of siderophile elements in its mantle; that is, there was no separation of metal from silicate (Fig. 3a). Not only would the lunar iron content derived from such a source be too high, but it is hard to see how a planet larger than Mars could escape differentiation into a separate core and mantle<sup>48</sup>. There is abundant evidence from over 60 varieties of iron meteorite that core formation occurs even in relatively small asteroidal bodies. Also, the absence of a core in the impactor would make it more difficult to place a lunar mass of material in orbit<sup>20–22</sup>. The objections to an undifferentiated chondritic impactor, and to an oxidized chondritic impactor containing no Fe–Ni metal, are discussed in more detail in ref. 49.

In this model the entire siderophile element depletion observed in lunar silicates has to be explained by core formation

FIG. 4 The maximum core size in the impactor is constrained by the similar abundances of W and Co in the Earth (●) and Moon (○). These imply that the impactor also had similar concentrations of W and Co. The maximum allowable core size (10 wt%) corresponds to the minimum metal/silicate partition coefficients ( $D^{M/S}$ ) for these elements, and the maximum depletion<sup>42</sup>. The minimum partition coefficients are calculated for a composition of 50 wt% S-rich metal and 50 wt% Fe-metal<sup>42,54</sup>; a larger amount of S-rich metal would reduce the partition coefficient of W too much relative to Co. The maximum depletion for these elements is derived from estimates of the uncertainties of the depletions<sup>42</sup>. The dashed line represents the depletions expected for a core size of 10 wt%, and this line just grazes the maximum depletions observed in the Earth and Moon.

in the Moon. Newsom<sup>42</sup> concluded that the observed lunar depletion could be explained by segregation of ~4–5.5 wt% Fe–Ni metal<sup>40,41,50</sup>, assuming segregation at low degrees of partial melting of the silicates (5–9%).

**Siderophile depletion in impactor mantle similar to Earth's mantle.** With the exception of the highly siderophile elements (Fig. 3b), this could be produced by segregation of a small (<10 wt%) core, assuming equilibrium between the impactor's core and mantle. In the absence of core–mantle equilibrium, as in the Earth, any size of core would be possible, including 30 wt%<sup>20–22</sup>. If the Moon formed from material with a siderophile element pattern characteristic of the Earth's mantle, including Earth-like abundances of highly siderophile elements, then segregation of additional metal (<0.2 wt%) is needed in the Moon to produce the observed lunar pattern<sup>42</sup>.

**Siderophile depletion in impactor mantle similar to present Moon.** Formation of the Moon from material with essentially its present abundance of siderophile elements constrains the amount of metal in the impactor that could produce the depletion. Assuming impactor core–mantle equilibrium and the largest possible depletion of Co and W in lunar silicates, the maximum size of the impactor core is ~10 wt% metal (Fig. 4). The composition of the impactor core is also constrained by the Co and W abundances. The metal/silicate partition coefficients<sup>51</sup> are lower for sulphur-rich metal (25–30% S), allowing larger core sizes than for sulphur-free metal (Fig. 3c). Assuming that the impactor core consists of both S-rich and S-poor metal, the fraction of S-rich metal in the core must be <50%. A larger amount of S-rich metal would reduce the partition coefficient for W too much relative to Co, and W would not have been depleted, as is observed for the shergottite parent body<sup>52,53</sup>. In this model, no metal segregation in the Moon is required to explain the siderophile abundances. If a lunar core exists, as indicated by the geophysical data, there must have been disequilibrium

between the core and the lunar mantle during core formation. *Siderophile depletion in impactor mantle greater than in the Moon.* This possibility is unlikely, as it requires siderophile elements to be added to the Moon from elsewhere. The moderately siderophile elements Co and W have similar abundances in the Earth's mantle and the silicate portion of the Moon (Fig. 4). If the impactor had W and Co abundances significantly below the lunar (and terrestrial) level, addition of terrestrial material would not bring the abundance up to the lunar level. The abundances of the highly siderophile elements could be consistent with the addition of a relatively large amount of terrestrial mantle material to the Moon (15–50%), although additional complications arise if the Earth's mantle already possessed its veneer of highly siderophile elements.

### Implications for the Earth

The implications for the Earth of the single impact origin of the Moon are considerable. The event probably triggered or enhanced complete melting of the Earth's mantle<sup>26</sup>. In addition to the accretion of the impactor's core, the impactor's mantle would have provided about 10% of the mass of the Earth's mantle.

For the second and third models above, with terrestrial or lunar siderophile abundances in the impactor, the implications for the siderophile element budget of the Earth depend on the fate of the metal core from the impactor. Models of the collision<sup>20–22</sup> indicate that most of the impactor core ends up in the Earth, with the metal penetrating the mantle and wrapping around the Earth's core. This would not disturb the siderophile abundance patterns already present in the Earth's mantle, but a significant amount of material from the impactor's core, enriched in siderophile elements, would probably have been vaporized and redistributed into the mantle. The detailed implications for terrestrial siderophile abundances depend on the fraction of the accreting metal core with small enough grain size to equilibrate with the mantle, but partial retention of metal from the impactor could explain the entire siderophile element pattern in the Earth's mantle<sup>49,54</sup>. Another variation on this theme states that the present abundances of highly siderophile elements in the Earth's mantle (the late veneer) result from the addition of a small portion of the impactor's core, while the rest of the impactor's core accreted to the Earth's core without significant interaction with the Earth's mantle. The Moon shows little evidence of a late veneer of siderophile elements, supporting an event unique to the Earth as the explanation for the abundances of the highly siderophile elements in the Earth's mantle.

To obtain the observed mantle abundances of the highly siderophile elements requires adding material with chondritic abundances equal to 0.74% of the mass of the Earth's mantle<sup>55</sup>. This can be achieved with 3–4% of the impactor's core, assuming that the total mass of the impactor is between 0.12 and 0.17 Earth masses, respectively. The percentage of the impactor core required depends on the size of the impactor, and is independent of the size of the impactor core because the highly siderophile elements from the impactor would be quantitatively concentrated in the metal. The amount of metal containing the siderophile elements added to the mantle is very small: 0.2 wt% of the Earth's mantle for an impactor core size of 31 wt%, and less than that for smaller cores.

As for the moderate siderophiles, the probable differentiation of the impactor into mantle and core would have depleted these elements in the impactor mantle to levels at or below terrestrial mantle values. Thus the addition of impactor mantle amounting to <10% of the mass of the terrestrial mantle would not significantly alter the terrestrial abundances of the moderately siderophile elements. The contribution of both moderately and highly siderophile elements from the impactor's core to the abundances in the Earth mantle would be only ~1%, insignificant compared with the 5–10% levels in the Earth's mantle.

# Conclusions

From these arguments we deduce that not only the dynamics, but the chemical properties of the Earth-Moon system can be explained by a low-velocity ( $5 \text{ km s}^{-1}$ ) collision with the Earth of a body of  $\sim 0.14$  Earth masses (larger than Mars) during the final stages of the accretion of the Earth from a hierarchy of planetesimals. The impacting body was already differentiated into a metallic core and silicate mantle; the material that ended up in the Moon was derived principally from the impactor's mantle, which must have been depleted in siderophile elements by core segregation, leaving siderophile abundances somewhere between lunar and present terrestrial mantle values. The core of the impactor was  $<10\%$  of its mass, if there was equilibrium between it and the mantle, and the fraction of S-rich metal in the impactor's core was  $<50\%$  of the core's mass. The core might have been larger, if the core and mantle were not in equilibrium. The impactor's mantle had volatile-element abundances similar to those of the terrestrial planets, and was enriched in FeO compared to the Earth.

The fate of the impactor's core has important implications for the abundances of siderophile elements in the Earth's mantle. The chondritic relative abundances of the highly siderophile elements can be explained if  $\sim 3\text{--}4\%$  of the impactor's core were mixed into the Earth's mantle, the remainder of the core accreting to the Earth's core without interacting with the mantle.

For fuller substantiation, the giant impact hypothesis requires more data, some of which can be collected only on future space missions. For example, the geochemical behaviour of the elements under the extreme conditions of the impact is poorly

understood and it is not clear how much of the depletion of volatile elements and enrichment of refractory elements in the Moon is a result of the impact. To answer this, we need more information on the overall composition of the lunar surface, which could be obtained by an orbiting probe; additional data on heat flow, which would put constraints on bulk composition; and seismic measurements to determine the size of the lunar core and confirm the density discontinuity at 500 km depth. Future lunar missions might obtain direct samples of the lunar mantle from the central peak of Copernicus where mantle rock has evidently been exposed by rebound following the impact that formed the crater.

On Earth, we need to know more about the chemistry of siderophile elements in the mantle, and more about the lower mantle, which remains largely unexplored. Further from home, mechanisms of planetary accretion have to be examined. This will require an understanding of the variations in the composition of the original nebula, which can be estimated from the geochemistry of Mercury, Venus and Mars. The forthcoming exploration of the martian moon, Phobos, and probes to distinct regions of the asteroid belt may also provide insights into the formation of the now-vanished hierarchy of planetesimals that accreted to form the terrestrial planets, and of the one that provided us with our unique and poetically inspiring Moon.  $\square$

# An automatic temperature cycler at an automatic savings.

**Low Price  
Quick Delivery**

## *TwinBlock™ System doubles your research flexibility to save your lab time and money.*

The **fully programmable** TwinBlock™ System can do the work of two temperature cyclers. That's because the TwinBlock System has two heating blocks under independent microprocessor control. So it can run two different, **totally independent** experiments simultaneously using as many as 29 samples in each test.

Laboratories around the world use Ericomp's temperature cyclers to heat and cool test samples automatically through repeated cycles for any of several user-defined time intervals and temperatures ranging from 25° to 100° Centigrade.

If a cost effective convenient alternative to temperature cycling is what your lab needs, then our general purpose microprocessor-controlled incubator is the ideal solution.

### **The TwinBlock System includes the following standard features:**

- Storage for 26 user-generated programs in non-volatile memory for quick recall even after the instrument is turned off (each program can have up to 20 chained profiles and each profile can be repeated automatically up to 9,999 times).

- Storage for up to 99 user generated, non-volatile time/temp profiles each of which can have up to 99 time/temp steps
- Sample tube temperature monitoring for very accurate set points, eliminating the need for vigorous additional calibration measurements (excellent closed loop control)
- Dual speed temperature ramps
- Concise operator guide/user manual which provides time-saving learning curve
- On-board chart recorder
- Warranty protection (extended coverage available)

## “There must be an easier way to synthesize DNA!”

You said it yourself.

We call it Gene Assembler® Plus.

To begin with, Gene Assembler Plus is truly easy to get to know. All operations are controlled with the help of an IBM computer and incredibly easy software. Furthermore, with Gene Assembler Plus there's no need to prepare reagents or mix solvents. They're all prepacked and ready to use.

During operation, you can rest assured that success is ahead. A built-in monitor

automatically registers the trityl concentration of each synthesis cycle. Coupling efficiency and yield are calculated for each cycle and results are displayed on the screen of your personal computer or printed out. If results differ from preset parameters, synthesis is automatically put on hold. This way you ensure a successful oligonucleotide synthesis without wasting expensive reagents or solvents.

Finally, we know that an easy-to-use synthesizer isn't the only key to successful DNA synthesis. That's why Pharmacia LKB is committed to providing you with all the help you may need ... from synthesis to final purification.

Why don't you contact us today to find out more about how to make DNA synthesis easier.

# An initiation site for meiotic gene conversion in the yeast *Saccharomyces cerevisiae*

Alain Nicolas\*, Douglas Treco, Neil P. Schultes & Jack W. Szostak

Department of Molecular Biology, Massachusetts General Hospital, Boston, Massachusetts 02114, USA

An initiation site for meiotic gene conversion has been identified in the promoter region of the *ARG4* gene of *Saccharomyces cerevisiae*. The chromosome on which initiation occurs is the recipient of genetic information during gene conversion.

CONVENTIONAL genetic analysis has failed to provide a clear understanding of the mechanism of homologous recombination in meiosis. The mechanism for initiation of recombination remains particularly controversial, as most of the genetic data can be explained by models that invoke either double-strand breaks<sup>1</sup> or single-strand nicks<sup>2</sup> as the initiating DNA lesion. The existence of specific sites for the initiation of recombination has been suggested<sup>3</sup> to explain the genetic phenomenon of polarity: a gradient in the frequency of gene conversion from one end of a gene to the other (reviewed in refs 4 and 5). No such site has been identified and characterized however. Here, and in the accompanying paper<sup>6</sup>, we describe the localization and characterization of a recombination initiation site near the *ARG4* gene of the yeast *S. cerevisiae*. The properties of this site provide evidence for the double-strand-break repair model<sup>1</sup> of meiotic recombination.

We have used classical genetic analysis of deletions constructed by recombinant DNA methods to map the *ARG4* initiation site. A diploid cell that is heterozygous at a mutant site (*m*/+) usually produces two *m* (mutant) spores and two + (wild-type) spores (a mendelian segregation). In some fraction of meioses, however, gene conversion events give rise to progeny where the ratio of + to *m* is 3:1 or 1:3 (non-mendelian segregation). In these cases the information at the position of the mutation on one chromatid of a pair of sister chromatids is lost and replaced with the corresponding information from its homologue. To search for an initiation site, we first re-examined the pattern of recombination within *ARG4*, followed by a deletion analysis to identify sequences essential for high levels of meiotic gene conversion within this gene.

## Polarity of gene conversion within *ARG4*

Meiotic recombination in the *ARG4* gene has been studied extensively by Fogel and colleagues (reviewed in ref. 7). The frequency at which an *arg4*<sup>-</sup> allele engages in gene conversion depends on its position, with the frequency diminishing from one end of the gene to the other. To eliminate the possibility that the variation in conversion frequency was a result of marker effects, silent base substitutions or strain background effects, we re-examined the pattern of recombination within *ARG4* using a set of alleles constructed *in vitro*. Seven mutant alleles were constructed from cloned *ARG4* DNA and transplanted into the yeast genome at the *ARG4* locus, without the addition of any other genetic material. All seven mutations destroy recognition sites for restriction enzymes. Six are insertions or deletions of two to four base pairs (bp) (Fig. 1) and one is a G→C mutation at position +3 of the coding region.

Strains carrying each of these *arg4*<sup>-</sup> alleles were crossed with wild-type (*ARG4*<sup>+</sup>) haploids, and tetrads were dissected to determine the gene conversion frequency of each allele (Fig. 1). There is a clear gradient in gene conversion frequencies, with

5' alleles having high frequencies and 3' alleles having much lower ones. The values range from 9.1% to 0.4% of total meioses. The gradient of conversion is seen even for mutations of the same physical nature. The *Acc* and *Aha* mutations, both of which are 2-bp additions, have a fourfold difference in conversion frequency. Likewise, the *Bcl* and *Bgl* mutations, both 4-bp additions, convert at frequencies that differ by a factor of eight.

Although all the addition and deletion mutants showed only 3<sup>+</sup>:1<sup>-</sup> and 1<sup>+</sup>:3<sup>-</sup> aberrant tetrad classes, the G→C mutation was characterized by a relatively high frequency of tetrads undergoing post-meiotic segregation (reviewed in ref. 4), amounting to about 20% of all aberrant segregations.

The pattern of meiotic recombination at *ARG4* was also examined in a diploid heteroallelic for the *RV* and *Bgl* mutations, which are separated by 1,015 nucleotides. Gene conversion accounted for 88% of the intragenic recombination events, and 83% of these were single-site events that included only the *RV* site. These data are consistent with the polarity observed in single-point crosses, and allowed us to consider the frequency of gene conversion at the *RV* site as being representative of the level of genetic recombination within *ARG4*.

These studies, using *in vitro* constructed mutations, confirm the original observations of polarity within *ARG4*<sup>7</sup>, and show that this phenomenon is independent of the particular genetic background and alleles used.

## Homozygous deletions

To identify DNA sequences that are important for gene conversion within *ARG4* we used deletion analysis of a 9-kilobase (kb) region that extends from 7.5 kb upstream of the gene to a position 172 bp 3' to the *ARG4* coding region. We expected three possible deletion phenotypes, assuming that a single site was responsible for the gene conversion gradient. First, deletions upstream of the initiation site or downstream of the *ARG4* marker being tested should have no effect on gene conversion. Second, deletions that remove or inactivate the site should lower the conversion frequency within *ARG4*. Finally, deletions that remove DNA between the site and the marker being assayed should increase the conversion frequency of that marker by moving the marker closer to the initiation site.

We have used the frequency at which the *arg4-RV* allele converts to monitor the effects of 11 different homozygous deletions. The conversion frequency of this marker is not affected by deletions that lie upstream of position -316 or downstream of position +345 ( $\Delta 1$ ,  $\Delta 2$ ,  $\Delta 3$  and  $\Delta 15$ , Fig. 2a). In contrast, deletions  $\Delta 4$ ,  $\Delta 5$ ,  $\Delta 6$ ,  $\Delta 7$ ,  $\Delta 8$  and  $\Delta 9$  (Fig. 2b) all reduce the frequency of gene conversion for *arg4-RV*. The reductions, which range from two to ninefold, are all significantly lower than the wild-type level of 7.4%. All these deletions have 3' endpoints between positions -316 and +1, a region that includes all of the *ARG4* promoter<sup>8</sup>.

These deletions define a site that is required for the high frequency of gene conversion at the 5' end of the *ARG4* gene. If this site is an initiation site, deletions between this site and

\* Present address: Laboratoire I.M.G. Batiment 400, Université Paris-Sud, 91405 Orsay-cedex, France.

a marker should increase the conversion frequency of that marker. We have used the *arg4-Bgl* and *-Dra* mutations to look for such an effect (Fig. 3). Deletion  $\Delta 14$  removes 980 bp of DNA from the coding region and moves the *Bgl* marker almost as close to the proposed initiation site as the *RV* marker is in the wild-type gene. In the presence of this homozygous deletion, gene conversion at the *Bgl* site increases from its normal frequency, 0.4%, to 7.2%, roughly the same as that at the *RV* site in non-deletion controls. Two control crosses confirm that sequences mapping to the region defined by the deletions in Fig. 2 are responsible for this effect. One of these extends the deletion by 142 bp further 5' than  $\Delta 14$  (deletion  $\Delta 13$ ), and the second extends it 316 bp further 5' than  $\Delta 14$  (deletion  $\Delta 12$ ). Gene conversion of *arg4-Bgl* was 1.2% with  $\Delta 13$ , and 1.0%

FIG. 1 Gene conversion frequencies for *in vitro* constructed *ARG4* mutations. Seven *arg4*<sup>-</sup> alleles were constructed *in vitro* and transplanted into the *S. cerevisiae* genome at the *ARG4* locus. The mutations denoted *Acc*, *RV*, *Bcl*, *Dra*, *Aha* and *Bgl* are small insertions or deletions that destroy the recognition sites for the restriction enzymes *AccI*, *EcoRV*, *BclI*, *DraIII*, *AhaI* and *BglII* respectively. The G→C mutation at position +3 is a single base substitution that destroys an *NspH* site. Nucleotide position +1 is the first base pair in the *ARG4* coding region<sup>8</sup>. The number of conversion events in each direction is listed separately, and combined to yield the conversion frequency. Of the ten tetrads showing post-meiotic segregation (p.m.s.) for the mutation at position +3, one was 5<sup>+</sup>:3<sup>-</sup> and nine were 3<sup>+</sup>:5<sup>-</sup>.

**METHODS.** Standard methods for manipulating and modifying DNA were used to construct the *ARG4* mutations<sup>20</sup>. Plasmid p(SPO13)2 was the source of *ARG4* DNA used in these studies<sup>21</sup>. The G→C transversion mutation was generated by oligonucleotide-directed mutagenesis<sup>22</sup> using a synthetic 25-mer with a single base difference from the wild-type *ARG4* sequence at the third base of the AUG initiation codon. All of the mutated plasmids were transformed into *Escherichia coli* strain NPS/RK2 (relevant genotype *argH1 leuB6 trpC1117 pyrF dam*<sup>-</sup>). The *argH1* mutation in this strain can be complemented by the wild-type *ARG4* gene<sup>23</sup>, but not by any of the seven mutant genes. All yeast strains used were derived by lithium acetate transformation<sup>24</sup> of the isogenic strains<sup>25</sup> MGA1 (*MAT $\alpha$  leu2-3, 112 ura3-52 his3 $\Delta$ 1 trp1-289*), MGA2 (*MAT $\alpha$  ura3-52 his3 $\Delta$ 1 trp1-289 ade2*), MGA3 (*MAT $\alpha$  leu2-3, 112 ura3-52 trp1-289*) and MGA11 (*MAT $\alpha$  leu2-3, 112 ura3-52 ade2*). Cycloheximide-resistant derivatives of MGA1 and MGA2 were selected on 10  $\mu$ g ml<sup>-1</sup> cycloheximide. The *ARG4* mutations were introduced into yeast either by the standard gene-transplacement technique<sup>26</sup> or by a co-transformation procedure<sup>27</sup>. Single *arg4*<sup>-</sup> colonies from each of the seven transformants were crossed to *ARG4*<sup>+</sup> yeast, diploids were selected, sporulated and the resultant asci were dissected to determine the gene conversion frequencies for each *arg4*<sup>-</sup> allele. The segregation of *ARG4* and at least five additional heterozygous markers was examined for each cross, and only tetrads displaying aberrant segregation at a single locus were scored as conversion events. Media and growth conditions were essentially as described<sup>28</sup>. Diploid cells were pregrown to a cell density of about  $8 \times 10^7$  cells ml<sup>-1</sup> in YPD (1% yeast extract, 2% Bacto-peptone, 2% dextrose), washed once in water and transferred to liquid sporulation medium at a cell density of  $2 \times 10^7$  cells ml<sup>-1</sup>. Sporulation was carried out at 30 °C with vigorous shaking in 1% potassium acetate, 0.1% Bacto-yeast extract, 0.05% dextrose plus any nutritional supplement required by the particular diploid. Spore viability typically >95%.

with  $\Delta 12$ ; these values are not significantly different from each other or from the value of 0.4% reported for the *Bgl* site in Fig. 1. These results indicate that the conversion frequency of *arg4-Bgl* can be increased by a factor of at least six by moving it closer to the conversion element (comparing  $\Delta 13$  with  $\Delta 14$ ), and that sequences between -139 and +3 are essential for the high frequency of gene conversion. In a similar experiment, we used *arg4-Dra*, which converts at a frequency of 2.8%. Upon deletion of 566 bp of DNA between positions -37 and +529 ( $\Delta 11$ ), the frequency of gene conversion at the *Dra* site increased to 6.2%, an increase of more than twofold over the wild-type frequency at this site, and a value that is not significantly different from the wild-type frequency for *arg4-RV*. The results of these internal deletion studies indicate that most, if not all of the conversion element is 5' to position -37, as both  $\Delta 14$  and  $\Delta 11$  can raise the frequency at which downstream alleles convert to a level indistinguishable from the frequency determined for *arg4-RV*. These results confirm the notion that the gradient in gene conversion frequency reflects the physical distance between a marker and the initiation site and not marker effects.

The above experiments place the 5' and 3' boundaries of the sequences that stimulate gene conversion between positions -316 and -37. We were therefore surprised that deletion  $\Delta 10$  (-316 to +3) did not affect conversion at the *RV* site (Fig. 2b). As ten deletions that remove all or part of this region have significant effects on gene conversion, we suspect that in the  $\Delta 10$  deletion, two sequences have been fused together to create a new sequence that can function to initiate gene conversion.

### Direction of information transfer

Deletion of an initiation site from one homologue should lead to a bias in the direction of information transfer (disparity) as only the wild-type chromosome can initiate gene conversion. In a cross that is heterozygous for the 142-bp deletion  $\Delta 9$  ( $\Delta 9$ , Fig. 2b; cross D9HET, Fig. 4), there is a fourfold excess of tetrads that are 3 $\Delta$ :1+ over those that are 1 $\Delta$ :3+, indicating that the wild-type DNA sequence that lies opposite the deletion is the preferred recipient of information in gene conversion. About half (562) of the tetrads reported for this cross were also heterozygous for *arg4-RV*. Six aberrant segregations at this site were observed, and all six were co-converted with the 142-bp heterology. An extra 10 conversion events involved only the deletion and did not include the *RV* site. These observations indicate that conversion events originate in or near the sequences removed by deletion  $\Delta 9$ .

A similar cross between two haploids carrying different deletions results in an 84-bp heterozygosity which includes sequences necessary for the expression of *ARG4* (cross  $\Delta 5/\Delta 6$ , Fig. 4). There is a 22:1 bias in the direction of information transfer in this cross, with the homologue that retains the sequences from -140 to -56 acting as the preferred recipient in gene conversion. We used two control crosses to show that not all insertion/deletion heterozygosities show this disparity (Fig. 4). One cross had a 137-bp insertion, and the other an 84-bp deletion in the *ARG4* coding sequence. Both of these heterozygosities fall within regions of the gene that are, on the basis of our deletion analysis, downstream of the initiation site. Both heterologies show a modest tendency to convert towards the deletion, or the shorter, of the two recombining *ARG4* regions, but in neither case is the ratio significantly different from an expected ratio of one. It seems that strong disparity is a property only of heterozygous deletions involving the initiation site.

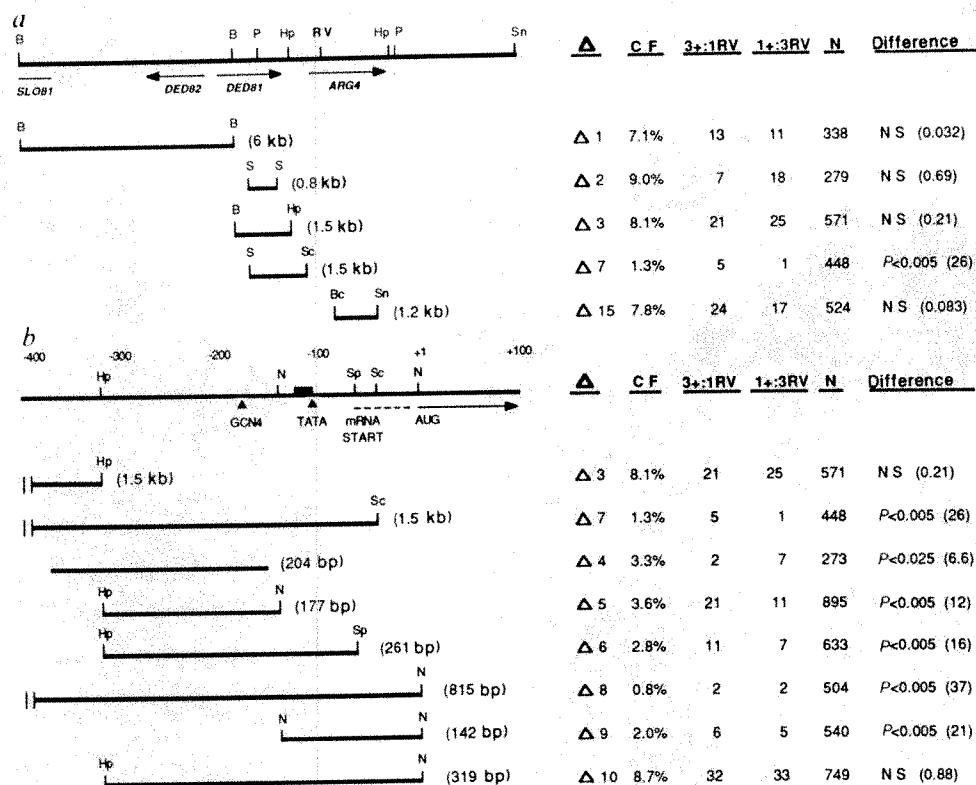

### Discussion

Several lines of evidence indicate that a region overlapping the *ARG4* promoter acts as an initiation site for meiotic recombination. First, deletion of the site abolishes the high frequencies of gene conversion seen at the 5' end of the *ARG4* gene. Second, deletions that move the site closer to a marker raise the frequency at which that marker engages in gene conversion. Third,

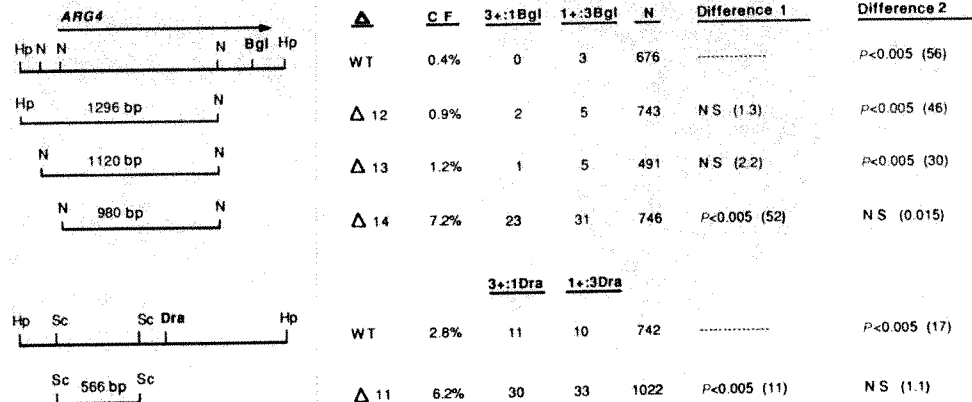

**FIG. 2** Effects of homozygous deletions on meiotic gene conversion at the *RV* site of *ARG4*. Solid black bars represent the DNA sequences deleted in each of the 11 crosses assayed. Positions of deletion breakpoints are numbered from the first base in the AUG codon of *ARG4* (position +1). The number of conversion events in each direction is listed separately, and combined to yield the conversion frequency (CF). *N* is the number of four-spore viable tetrads analysed; + indicates wild-type information; *RV* indicates the mutant site. The column labelled 'difference' indicates whether the conversion frequency is significantly different from the value of 7.4% determined for the *RV* site (Fig. 1). The level of significance is indicated by the *P*-value. Also listed are the *G*-values (parentheses) that were used in the significance testing (calculated using the *G*-test of independence<sup>29</sup>). NS, no significant difference. B, *Bam*HI; Bc, *Bcl*I; Hp, *Hpa*I; N, *Nsp*HI; P, *Pst*I; RV, *Eco*RV; S, *Sal*I; Sc, *Sac*I; Sn, *Sna*BI; Sp, *Ssp*I. a, A 13.5-kb region surrounding the *ARG4* gene and a partial restriction map is shown. Arrows indicate the directions of transcription for the *DED81*, *DED82* and *SLO81* genes. b, A 700-bp region around the 5' end of the *ARG4* gene is shown. The 3' endpoints of  $\Delta 3$  and  $\Delta 7$  are shown for orientation purposes. The positions of the experimentally determined *GCN4*-binding site<sup>30</sup>, a possible TATA element, and the measured mRNA start site are indicated. The black box represents a run of 14 A residues (*A*<sub>14</sub>). All of these elements have been proposed to be involved in transcription of *ARG4*<sup>31</sup>.

**METHODS.** Deletions (except  $\Delta 4$  and  $\Delta 10$ ) were constructed by cutting with the restriction enzymes indicated.  $\Delta 4$  is a spontaneous deletion of 204 bp that arose by selecting for *arg*<sup>+</sup> function in *E. coli*<sup>23</sup>.  $\Delta 10$  was constructed by oligonucleotide-directed mutagenesis<sup>22</sup> using a synthetic 48-mer that spans the deletion breakpoints. Plasmids containing these deletions were subjected to DNA sequence analysis to ensure that no additional sequences were lost or added. This analysis revealed that  $\Delta 8$  extended 55 bp further upstream than the *Sal*I site at position -0.76 kb. Haploid strains were constructed with the *URA3* gene<sup>32</sup> inserted at various positions within and upstream of *ARG4*. Deletions were introduced by co-transformation<sup>27</sup> with a CEN plasmid followed by screening for loss of the *ura*<sup>+</sup> phenotype, and then by Southern analysis for the presence of the deletion. Genetic analysis of the *URA3* inserts revealed two essential genes upstream of *ARG4*, *DED81* and *DED82*, and one gene, *SLO81* which results in an extremely slow growth

**FIG. 3** Effects of homozygous deletions on meiotic gene conversion at the *Bgl*I (deletions  $\Delta 12$ ,  $\Delta 13$  and  $\Delta 14$ ) and *Dra* sites ( $\Delta 11$ ) in *ARG4*. Solid black bars represent DNA sequences deleted in each of the experimental crosses. The numbers of conversion events in each direction are listed separately and are combined to yield the conversion frequency. The data for wild-type (WT) levels of conversion at these sites are taken from Fig. 1. The column headed 'difference 1' indicates whether the conversion frequency is significantly different from the wild-type level at that particular site (data from Fig. 1). + indicates wild-type information; *Bgl*I and *Dra*I indicate the mutant sites. The column headed 'difference 2' indicates whether the conversion frequency is significantly different from the wild-type frequency at the *RV* site (data from Fig. 1). Abbreviations and statistical methods are as in Fig. 2. Because deletions  $\Delta 11$ ,  $\Delta 12$ ,  $\Delta 13$  and  $\Delta 14$  confer an *arg*<sup>-</sup> phenotype, *ARG4*

phenotype. All diploids used in the deletion analysis contain a 10.5 kb insert in the *URA3* gene at its normal chromosomal position<sup>33</sup>. This insert, designated *dup*<sup>+</sup>, contains sequences from -7.3 kb to +5.2 kb around *ARG4*, but without a 2-kb fragment from -316 bp to +1,745 bp that carries the *ARG4* gene<sup>8</sup>. The *dup*<sup>+</sup> construct complements deficiencies created upon disruption of *DED81* or *DED82*. Yeast transformation and tetrad analysis were as described in the Fig. 1 legend. Deletions  $\Delta 6$  through  $\Delta 10$ , and  $\Delta 15$  confer an *arg*<sup>-</sup> phenotype to yeast cells. The *ARG4* genotype of meiotic progeny was determined by allele testing, using a pair of tester strains carrying the *arg4-RV* mutation. Original dissection plates were printed onto a lawn of cells that were *arg4-RV*, *thr4*<sup>-</sup> and either *MATa* or *MATα*. After mating for 16 h at 30 °C, the plates were printed onto minimal media and irradiated with a 354 nm UV light source for 1 min at distance of 1 m. Cells that are *arg4-RV* cannot give rise to *arg*<sup>+</sup> papillae by recombination with an *arg4-RV* tester. All tetrads showing non-mendelian segregation were retested with an *arg4-RV* and other *arg4*<sup>-</sup> testers to ensure that *arg4*<sup>-</sup> allele was not generated by ectopic recombination with the *dup*<sup>+</sup> locus at *URA3* on chromosome V. Such events constitute ≤0.5% of all gene conversion events at *ARG4* (data not shown).

genotypes were scored as described in the Fig. 2 legend, using *arg4-Bgl* or *arg4-Dra* tester strains. For  $\Delta 11$  and  $\Delta 14$ , the data are pooled from crosses with and without *dup*<sup>+</sup> homozygous. The *dup*<sup>+</sup> genotype had no significant effect on the gene conversion frequency (data not shown).

heterozygous deletions show disparity of gene conversion, as expected when initiation occurs preferentially on one chromosome. Fourth, the initiation site is co-converted with the markers upon which it acts, which is consistent with recombination events starting at the initiation site and extending for variable distances away from the site. Finally, as we show in the accompanying paper<sup>6</sup>, we are able to detect the transient appearance of double-strand breaks at the initiation site during meiosis.

The property of disparity is important in considering models for initiation. We find that the chromosome on which events are initiated is the recipient of information in gene conversion. This is consistent with studies on meiotic hotspots in other fungi (for example, the *M26* mutation in the *ADE6* gene of *Schizosaccharomyces pombe*<sup>9</sup>, the *YS17* mutation in the *BUFF* locus of *Sordaria brevicollis*<sup>10</sup>, and the *cog*<sup>+</sup> variant near the *HIS3* gene of *Neurospora crassa*<sup>11</sup>). It has also recently been shown<sup>12</sup> that a yeast centromere can act to inhibit adjacent sequences from acting as recipients, but not donors, of information during meiotic gene conversion. The simplest explanation for this phenomenon is that the centromere acts in *cis* to inhibit initiation.

It therefore seems to be a general phenomenon that the chromosome on which initiation occurs is the recipient of information in gene conversion. This is inconsistent with the original Aviemore model<sup>2</sup> for recombination, in which a single-strand displaced from the initiating chromosome is transferred to the recipient chromosome. It is, however, consistent with either the modified Radding model<sup>13</sup>, in which a single-stranded gap on the initiating chromosome is repaired using information from the intact donor chromosome, or with the double-strand-break repair model<sup>1</sup>, in which conversion occurs by repair of a double-strand gap on the initiating chromosome using information on the intact donor chromosome.

The inevitable evolutionary consequence of a system in which initiation sites are the preferred recipients in gene conversion is that the sequences will tend to be lost as a result of the event itself. It is paradoxical that sequences that stimulate recombination are lost as a mechanistic consequence of this process, especially as studies on chromosome segregation in meiosis I have shown that recombination is essential for proper chromosome disjunction (reviewed in ref. 14). A possible solution to this paradox is that by coupling the signals for recombination to those for a cellular process that is under strong selective

pressure (for example transcription), any loss of initiation sites for recombination that may occur is compensated for by selection to maintain functional promoters.

The region that we have identified as the initiation site overlaps with the *ARG4* promoter. *ARG4* transcripts increase by 5- to 10-fold within one hour of transfer to sporulation medium (data not shown). Deletions that remove sequences essential for transcription of the *ARG4* gene and give rise to an *arg*<sup>-</sup> phenotype are highly deficient in *ARG4* transcripts in meiosis and show decreased conversion. With the exception of  $\Delta 10$ , which we believe creates a cryptic initiation site, no deletion that destroys any part of the promoter is without an effect on gene conversion.

In *S. cerevisiae*, a relationship between transcription and recombination has been demonstrated for mating-type switching<sup>15</sup> and for the *HOT1* site<sup>16</sup>, a sequence that stimulates mitotic recombination and consists of the essential sequences for ribosomal DNA transcription. Mitotic recombination between duplicated *GAL10* genes has recently been shown to be strongly stimulated by galactose-induced transcription (B. Thomas and R. Rothstein, personal communication). At present, however, we cannot eliminate the possibility that the *ARG4* promoter and conversion element merely overlap, or that the conversion element is a specific DNA sequence that stimulates recombination in the context of an active promoter.

It is important to note that gene conversion is decreased, but not abolished, in the absence of the initiation site that we have identified. The deletions that have the strongest effects,  $\Delta 7$ ,  $\Delta 8$ , and  $\Delta 9$ , still allow 1-2% gene conversion at the *RV* site. This background of gene conversion is probably due to initiation at other sites.

One of the major unanswered questions about meiotic recombination is to what extent heteroduplex DNA contributes to gene conversion. In single-strand initiation models<sup>2,13</sup>, all conversion occurs by heteroduplex formation followed by mismatch repair. In the double-strand-break repair model<sup>1</sup>, gene conversion can occur either by double-strand gap repair or by mismatch repair of heteroduplex DNA. Some heteroduplex DNA is known to form, as post-meiotic segregation is a well-documented phenomenon (reviewed in refs 4 and 5). Studies of post-meiotic segregation suggest that a minimum of 20-30% of all gene conversion events (and perhaps twice as many) between positions +3 and +341 go through a heteroduplex intermediate<sup>17</sup>. The suggestion that long regions of heteroduplex DNA can form

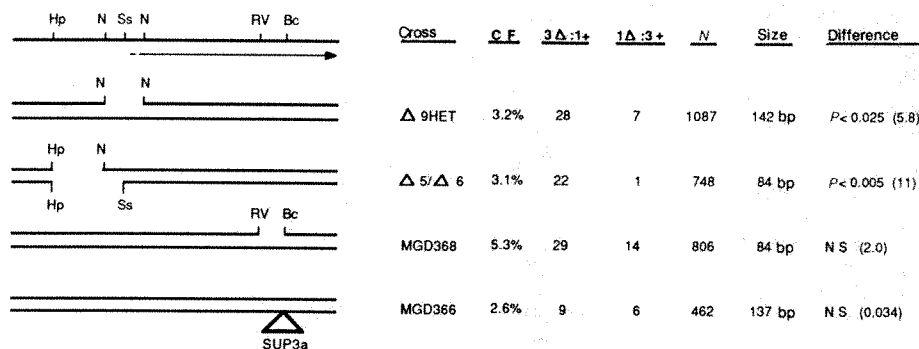

FIG. 4 Gene conversion of heterozygous deletions/insertions at *ARG4*. Data for  $\Delta 9$ HET is combined data from two similar crosses (MGD324 and MGD184), one of which (MGD324) was also heterozygous for *arg-RV* in *trans* to the deletion (see text). Both crosses displayed a similar bias in directionality of conversion for the 142 bp deletion (13 3Δ:1<sup>+</sup> and 3 1Δ:3<sup>+</sup> in MGD324 and 15 3Δ:1<sup>+</sup> and 4 1Δ:3<sup>+</sup> in MGD184). Cross  $\Delta 5/\Delta 6$  is described in the text. Conversion events in each direction are listed separately, but are combined to yield the frequency at which the heterology engages in gene conversion. Definitions and abbreviations are as in the Fig. 2 legend.  $\Delta$  indicates the deletion genotype, + denotes the wild-type configuration. The column headed

'difference' indicates the significance of the deviation from an expected ratio of one for the two conversion classes.

METHODS. Abbreviations and statistical methods are as described in the legend to Fig. 2, except that Yates' correction for small sample size was used in the calculation of  $G_{adj}^{29}$ . The 84-bp deletion that is heterozygous in MGD368 was created by digesting *ARG4* DNA with *EcoRV* and *BclI*, filling in the overhanging ends with T4 DNA polymerase and religating. The *SUP3a* fragment used in cross MGD366, a kind gift from Dr R. Rothstein, was inserted as a 137-bp *BamHI* fragment into the *BclI* site of *ARG4*. Yeast co-transformation and genetic analysis was as described in the Fig. 2 legend.

next to a region of double-strand-gap-repair is supported by the finding of extensive single-stranded DNA next to a double-strand break at the *ARG4* initiation site<sup>6</sup>, and by genetic analysis of linear and gapped plasmid DNA after transformation into yeast<sup>18,19</sup>.

The identification of a naturally occurring initiation site for gene conversion is a first step in the molecular analysis of meiotic

recombination. The further characterization of this sequence within and outside its normal context will contribute to our understanding of how initiation is regulated. By focusing on this DNA sequence throughout meiosis, intermediates in the initiation event can be identified and characterized, allowing us to establish the molecular nature of initiation and distinguish experimentally between the current models for recombination.

# Transcription activation by the adenovirus E1a protein

James W. Lillie & Michael R. Green

Department of Biochemistry and Molecular Biology, Harvard University, 7 Divinity Avenue, Cambridge, Massachusetts 02138, USA

The adenovirus E1a protein stimulates transcription of a wide variety of viral and cellular genes. It is shown here that E1a has the two functions characteristic of a typical cellular activator: one direct E1a to the promoter, perhaps by interacting with a DNA-bound protein, and the other, an activating region, enables the bound activator to stimulate transcription.

RECENT experiments have defined two functional regions of cellular transcription activators<sup>1–3</sup>. One, the 'binding region', directs the protein to DNA, enabling the other, the 'activating region', to interact with a component of the transcription complex to stimulate transcription. These regions are modular: each is a separable, functional unit that can be joined to the complementary region of an unrelated activator to create a functional hybrid activator<sup>1</sup> (reviewed in ref. 3). In most instances the binding region interacts directly with a specific DNA sequence, but in some cases the binding region recognizes a DNA-bound protein<sup>4–10</sup>. The binding region determines the activator's specificity by targeting the protein to only those promoters that have the appropriate binding site. The activating regions are short acidic fragments of no specific primary sequence<sup>11–14</sup>.

The adenovirus E1a protein (E1a) is a powerful transcription activator that is required for the expression of viral early genes<sup>15,16</sup>. Several lines of evidence suggest that E1a is atypical. First, E1a stimulates transcription of a wide variety of viral and cellular genes that lack a specific promoter element required for induction. Second, E1a enhances expression of genes transcribed by both RNA polymerase II and III (reviewed in ref. 17). Third, E1a does not bind a specific DNA sequence<sup>18</sup>. These differences suggest that E1a functions by a novel mechanism. It has been proposed, for example, that E1a stimulates transcription indirectly by converting cellular transcription factors from

an inactive to an active form<sup>19–22</sup>. Despite these apparent differences we present evidence here that E1a functions like a typical cellular activator.

## DNA-bound E1a activates transcription

Previous studies have shown that a small, highly conserved E1a region (designated region 3, amino acids 140–189; see ref. 23 and Fig. 6b) is necessary, and in some instances sufficient, to activate transcription<sup>24–30</sup>. Figure 1 shows that an E1a fragment containing region 3 activates transcription in mammalian cells when bound artificially to the promoter through the DNA-binding region of another activator. For this experiment, we constructed a plasmid that expresses E1a amino acids 121–223 fused to the GAL4 DNA-binding domain, GAL4(1–147). GAL4-E1a contains the GAL4 sequences required to recognize the GAL4-binding site, but lacks the GAL4 sequences that enable promoter-bound GAL4 to activate transcription *in vivo*<sup>11,12,31–36</sup>. The activity of GAL4-E1a is measured following cotransfection with a 'reporter' plasmid containing the chloramphenicol acetyltransferase (CAT) gene linked to a promoter, with or without inserted GAL4 sites.

Figure 1a shows that GAL4-E1a activates the adenovirus E4 promoter, which lacks GAL4 sites, but does so more efficiently if GAL4 sites are present (Fig. 1a, GAL4-E1a; compare E4 and GAL4/E4 promoters). As expected, wild-type E1a, which lacks

the GAL4 DNA-binding domain, activates the E4 and GAL4/E4 promoters comparably (Fig. 1a, E1a; compare E4 and GAL4/E4 promoters). Binding GAL4(1-147) alone does not enhance activation, because GAL4(1-147) lacks an activating region<sup>11</sup> (Fig. 1a).

Insertion of GAL4 sites dramatically increases activation of two other promoters. The mouse mammary tumour virus (MMTV) promoter is activated weakly by GAL4-E1a but the

insertion of GAL4 sites increases activation at least 100-fold (Fig. 1b). We also tested a 'core' promoter, created by inserting a double-stranded oligonucleotide bearing the adenovirus E1b TATA box upstream of the CAT gene. This E1bTATA promoter is not activated detectably by wild-type E1a (data not shown) and activation by GAL4-E1a is detectable only if GAL4 sites are present (Fig. 1c). (We note that weak activation of the E1b TATA box has been observed in virus infection experiments<sup>37</sup>).

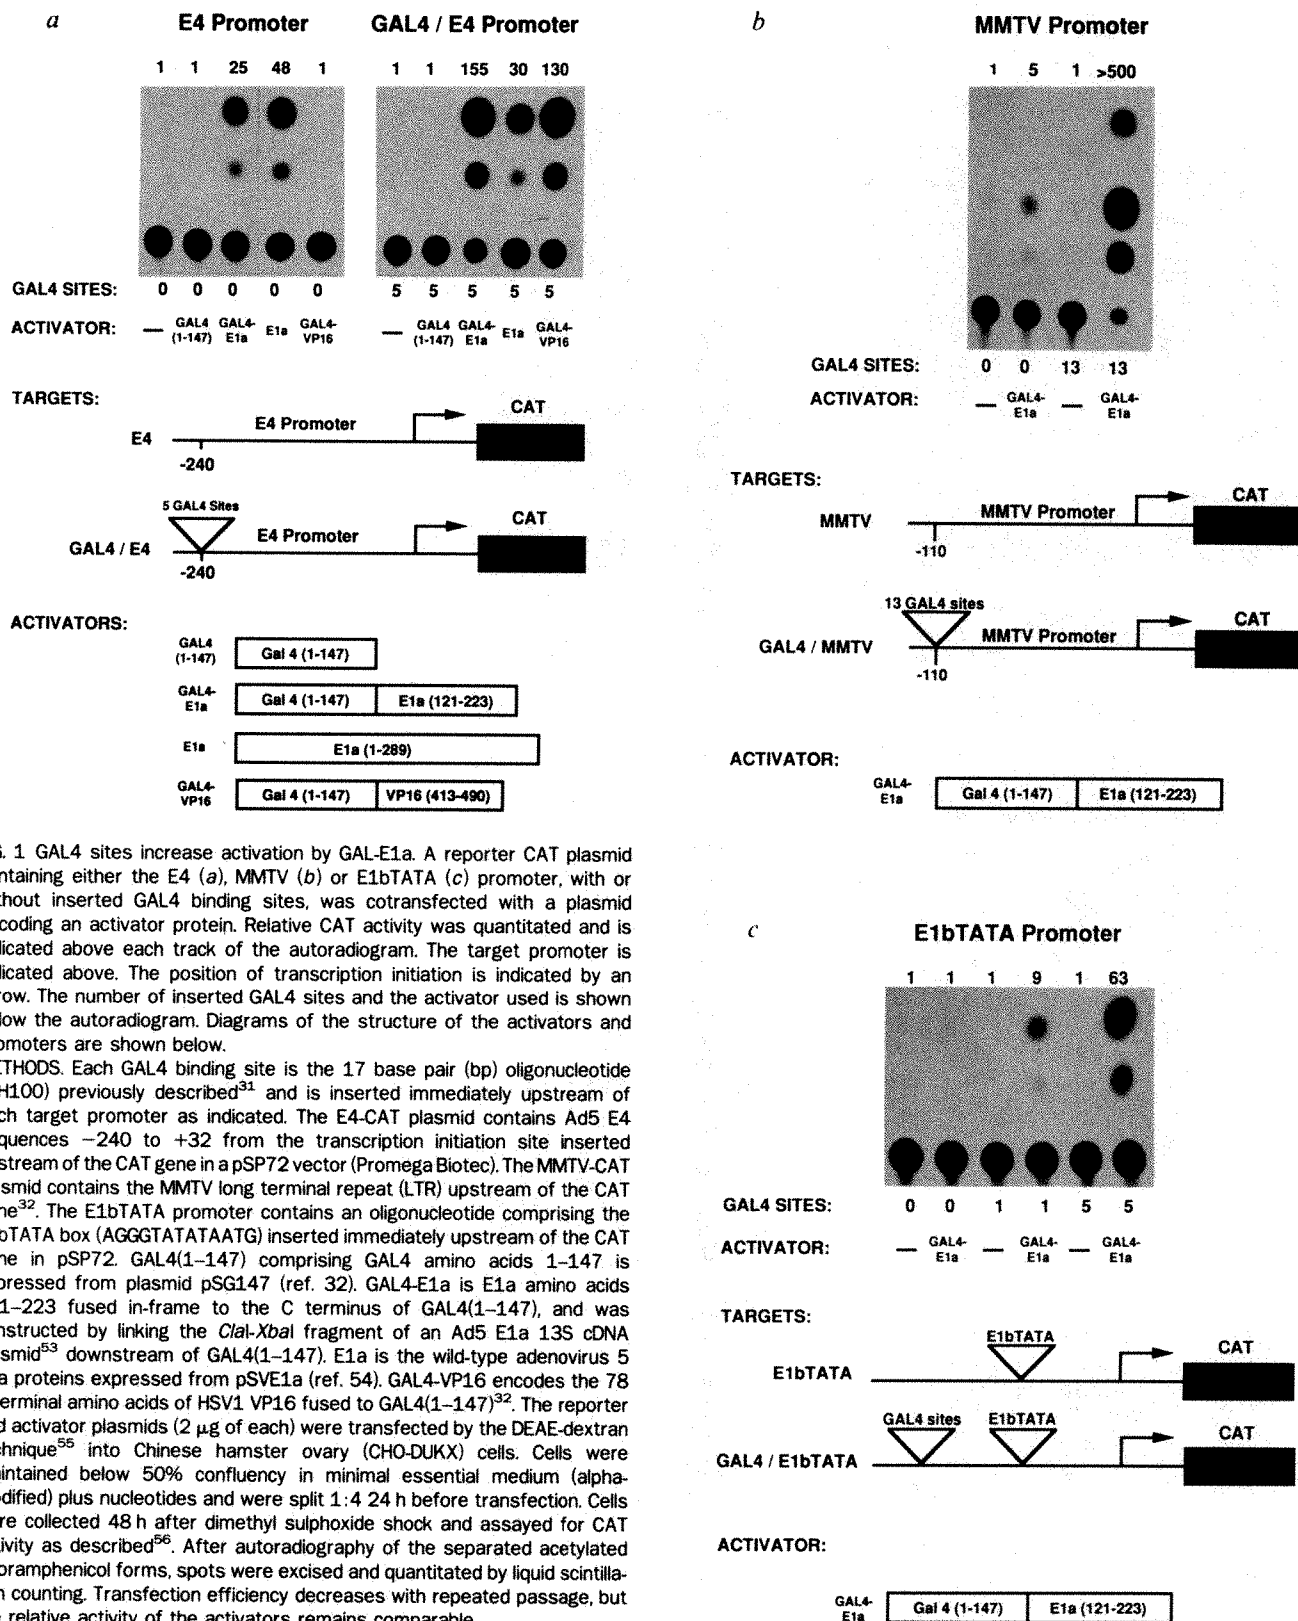

FIG. 1 GAL4 sites increase activation by GAL-E1a. A reporter CAT plasmid containing either the E4 (a), MMTV (b) or E1bTATA (c) promoter, with or without inserted GAL4 binding sites, was cotransfected with a plasmid encoding an activator protein. Relative CAT activity was quantitated and is indicated above each track of the autoradiogram. The target promoter is indicated above. The position of transcription initiation is indicated by an arrow. The number of inserted GAL4 sites and the activator used is shown below the autoradiogram. Diagrams of the structure of the activators and promoters are shown below.

**METHODS.** Each GAL4 binding site is the 17 base pair (bp) oligonucleotide (MH100) previously described<sup>31</sup> and is inserted immediately upstream of each target promoter as indicated. The E4-CAT plasmid contains Ad5 E4 sequences -240 to +32 from the transcription initiation site inserted upstream of the CAT gene in a pSP72 vector (Promega Biotec). The MMTV-CAT plasmid contains the MMTV long terminal repeat (LTR) upstream of the CAT gene<sup>32</sup>. The E1bTATA promoter contains an oligonucleotide comprising the E1bTATA box (AGGGTATATAATG) inserted immediately upstream of the CAT gene in pSP72. GAL4(1-147) comprising GAL4 amino acids 1-147 is expressed from plasmid pSG147 (ref. 32). GAL4-E1a is E1a amino acids 121-223 fused in-frame to the C terminus of GAL4(1-147), and was constructed by linking the *Cla*I-*Xba*I fragment of an Ad5 E1a 13S cDNA plasmid<sup>53</sup> downstream of GAL4(1-147). E1a is the wild-type adenovirus 5 E1a proteins expressed from pSVE1a (ref. 54). GAL4-VP16 encodes the 78 C-terminal amino acids of HSV1 VP16 fused to GAL4(1-147)<sup>32</sup>. The reporter and activator plasmids (2 µg of each) were transfected by the DEAE-dextran technique<sup>55</sup> into Chinese hamster ovary (CHO-DUKX) cells. Cells were maintained below 50% confluency in minimal essential medium (alpha-modified) plus nucleotides and were split 1:4 24 h before transfection. Cells were collected 48 h after dimethyl sulphoxide shock and assayed for CAT activity as described<sup>56</sup>. After autoradiography of the separated acetylated chloramphenicol forms, spots were excised and quantitated by liquid scintillation counting. Transfection efficiency decreases with repeated passage, but the relative activity of the activators remains comparable.

Although activation of the E1bTATA promoter is enhanced by a single GAL4 site, the presence of additional GAL4 sites amplifies the response—presumably by increasing the number of bound GAL4-E1a molecules (Fig. 1c). Taken together, these results indicate that binding E1a to DNA (or binding E1a more efficiently to DNA) enhances its ability to activate transcription. This in turn indicates that E1a may function naturally in the vicinity of the promoter.

### E1a contains an activating region

Figures 2, 3 and 4 show that E1a contains a powerful activating region required for the activation of promoters that contain GAL4 sites and those that lack them. Deletion analysis shows that E1a amino acids 139–149 (see Fig. 6c) are essential for the activity of GAL4-E1a. In these experiments, we compare the activity of several N-terminal deletion mutants of the E1a fragment 121–223. As the stability of similar proteins with different

N-terminal sequences varies greatly<sup>38,39</sup>, and as large variations in protein stability would distort comparisons, each derivative used in these and subsequent experiments begins with the same 147 amino acids, GAL4(1–147), even when the target promoter lacks GAL4 sites.

Removal of E1a amino acids 140–185 (most of region 3) abolishes GAL4-E1a's activity, whether or not GAL4 sites are present (Fig. 2a, GAL4-E1a $\Delta$ 3) even when 10 times more DNA is transfected (data not shown). In contrast, deletion of E1a amino acids 121–132 (most of region 2; see ref. 23 and Fig. 6b) does not affect GAL4-E1a's activity on either promoter (Fig. 2b, GAL4-E1a $\Delta$ N132). Deletion of the remaining six amino acids of region 2 contiguous to region 3 reduces activation slightly (Fig. 2b, GAL4-E1a $\Delta$ N138). Further deletion of the first 10 amino acids of region 3 abolishes GAL4-E1a's activity on both promoters (Fig. 2b, GAL4-E1a $\Delta$ N149), even when 10 times more DNA is transfected (data not shown). These results indi-

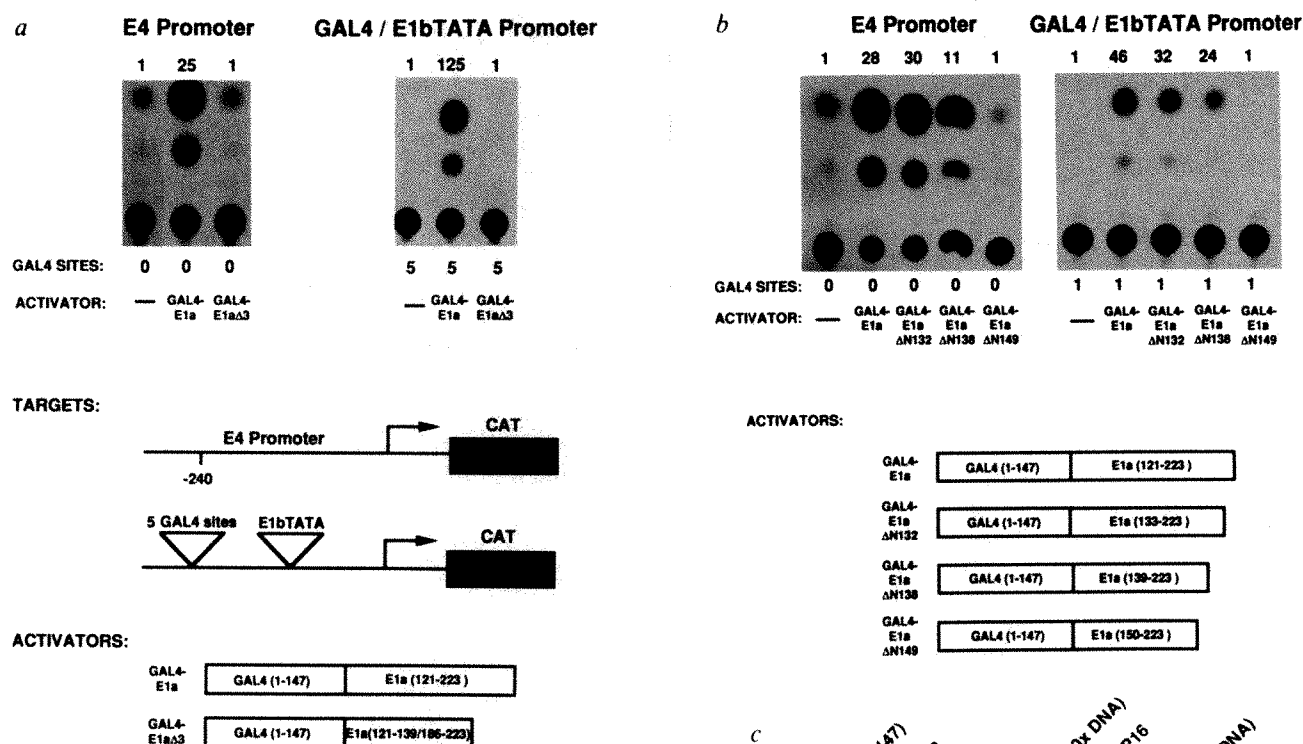

FIG. 2 E1a amino acids 139–149 are essential for activation of promoters with and without GAL4 sites. *a*, *b*. A reporter CAT plasmid containing the E4 or GAL4/E1bTATA promoter was cotransfected with a plasmid encoding the activator indicated below each track of the autoradiogram. Relative CAT activity was quantitated and is indicated above each track. *c*. Protein levels of GAL4-E1a derivatives. <sup>35</sup>S-labelled GAL4-E1a derivatives from transfected COS cells were immunoprecipitated with an anti-GAL4(1–147) antibody (a gift of I. Sadowski) and fractionated on a 10% SDS-polyacrylamide gel. The transfected activator is indicated above each lane. Relative molecular mass markers are indicated on the left.

**METHODS.** Transfections were performed as described in the Fig. 1 legend. Each activator is a derivative of GAL4-E1a. GAL4-E1a $\Delta$ 3 lacks the 13S-specific amino acids of region 3, amino acids 140–185 (see Fig. 6b), and was constructed by replacing the *Clal*-*Xba*I fragment of GAL4-E1a with the *Clal*-*Xba*I fragment of an Ad5 12S cDNA plasmid<sup>53</sup>. GAL4-E1a $\Delta$ N132 and GAL4-E1a $\Delta$ N138 are progressive 5' *Bal*/31 deletions of the 13S cDNA *Clal*-*Xba*I fragment, fused in-frame to GAL4(1–147).  $\Delta$ N132 begins at Ad5 nucleotide 956, E1a amino acid 133;  $\Delta$ N138 begins at Ad5 nucleotide 973, amino acid 139. GAL4-E1a $\Delta$ N149 contains the *Sma*I-*Xba*I fragment of the 13S cDNA plasmid fused to GAL4(1–147) and begins at Ad5 nucleotide 1010, amino acid 150. COS cells transfected using the DEAE-dextran procedure were labelled with 200  $\mu$ Ci ml<sup>-1</sup> of [<sup>35</sup>S]methionine for 3 h, 72 h after the dimethyl sulphoxide shock. Subsequently, whole-cell lysates were cleared with preimmune serum and *Staphylococcus aureus* protein A, the anti-GAL4(1–147) antibody added, and the immune complexes purified and fractionated

on a 10% SDS-polyacrylamide gel. In parallel, unlabelled whole-cell lysates prepared from COS cells cotransfected with a plasmid encoding each activator and the GAL4-E1bTATA reporter CAT plasmid were assayed for CAT activity. The results obtained in COS cells were identical to those obtained in CHO cells (data not shown).

cate that E1a amino acids 139–149 (region 3) are essential for GAL4-E1a's activity on promoters containing or lacking GAL4 sites.

To confirm that the above results reflect differences in activity of the GAL4-E1a derivatives, and not variations in protein concentration, we measured the level of each activator after transfection. Figure 2c shows that the various GAL4-E1a derivatives are expressed comparably and previous studies have shown that proteins of this size will enter the nucleus by passive diffusion<sup>40–41</sup>.

Figure 3 demonstrates that E1a amino acids 139–149 can be replaced by the acidic activating region of an unrelated activator. The herpes simplex virus 1 (HSV1) VP16 protein is a typical activator in that it contains a promoter-binding function and an acidic activating region<sup>42</sup>. The VP16 activating region is particularly powerful<sup>32</sup>. Fusion of VP16's activating region to the C terminus of GAL4-E1aΔN149 restores its ability to activate the E4 promoter (Fig. 3, compare GAL4-E1aΔN149 and GAL4-E1aΔN149-VP16). (GAL4-E1aΔN149-VP16 is expressed at a higher level than GAL4-E1aΔN149, Fig. 2c, but this is not sufficient to account for the difference in activity.) Thus, the acidic activating region of the HSV1 VP16 protein can substitute for the natural activity of E1a amino acids 139–149 (as assayed on the E4 promoter), although these two protein fragments bear no obvious sequence similarity. We conclude that this portion of E1a functions solely as an activating region. This experiment is in essence a 'domain swap'<sup>1,13,32,33,43–45</sup>.

FIG. 3 E1a amino acids 139–149 function as an activating region. A reporter CAT plasmid containing the E4 promoter was cotransfected with a plasmid encoding the activator indicated below each track. Relative CAT activity was quantitated and is indicated above each track.

METHODS. Transfections were performed as described in the Fig. 1 legend. GAL4-E1a and GAL4-E1aΔN149 are described in the legends to Figs 1 and 2, respectively. GAL4-E1aΔN149-VP16 contains the 78 C-terminal amino acids of the HSV1 VP16 protein fused in-frame to the C terminus of GAL4-E1aΔN149.

Finally, GAL4-E1a is a powerful activator, consistent with the notion that E1a, a potent activator, contains a strong activating region. The GAL4/E1bTATA promoter allows us to gauge the strength of E1a's activating region, as transcription is not detectable in the absence of GAL4 sites (Fig. 4). In this assay, E1a's activating region is at least 20 times stronger than the activating regions of either wild-type GAL4 or the GAL4 derivative, GAL4-B17 (Fig. 4, GAL4, GAL4-B17; ref. 12). In fact, the activity of GAL4-E1a is only twofold less than that of GAL4-VP16, which contains the strongest known activating region<sup>32</sup> (Fig. 4). The strength of E1a's activating region indicates that its activity is not the adventitious result of fusion to GAL4-(1–147).

### E1a contains a promoter-binding region

Like other activating regions, the VP16 activating region must be positioned in the vicinity of the promoter to function (reviewed in ref. 3). Thus, an important implication of the experiment shown in Fig. 3 is that GAL4-E1aΔN149 must contain an activity that directs the VP16 activating region to the wild-type E4 promoter. Neither the GAL4 binding domain, nor the VP16 activating region of GAL4-E1aΔN149-VP16, can provide this activity as GAL4-VP16 fails to activate the E4 promoter

FIG. 4 E1a contains a powerful activating region. A reporter CAT plasmid, containing the E1bTATA promoter with a single GAL4 site inserted immediately upstream, was cotransfected with one of several plasmids that encode an activator. Relative CAT activity was quantitated and is indicated above each track. The E1bTATA promoter is activated detectably by both wild-type GAL4 and GAL4-B17 if an additional four GAL4 sites are inserted upstream, but not as efficiently as it is activated by GAL4-E1a (data not shown).

METHODS. Transfections were as described in the Fig. 1 legend. GAL4(1–147), GAL4-VP16 and GAL4-E1a are as described in Fig. 1. GAL4 is the wild-type GAL4 protein, amino acids 1–881, expressed from pSG4 (ref. 32). GAL4-B17 encodes an acidic *Escherichia coli* sequence fused to GAL4(1–147) and is expressed from pSGB17 (ref. 32).

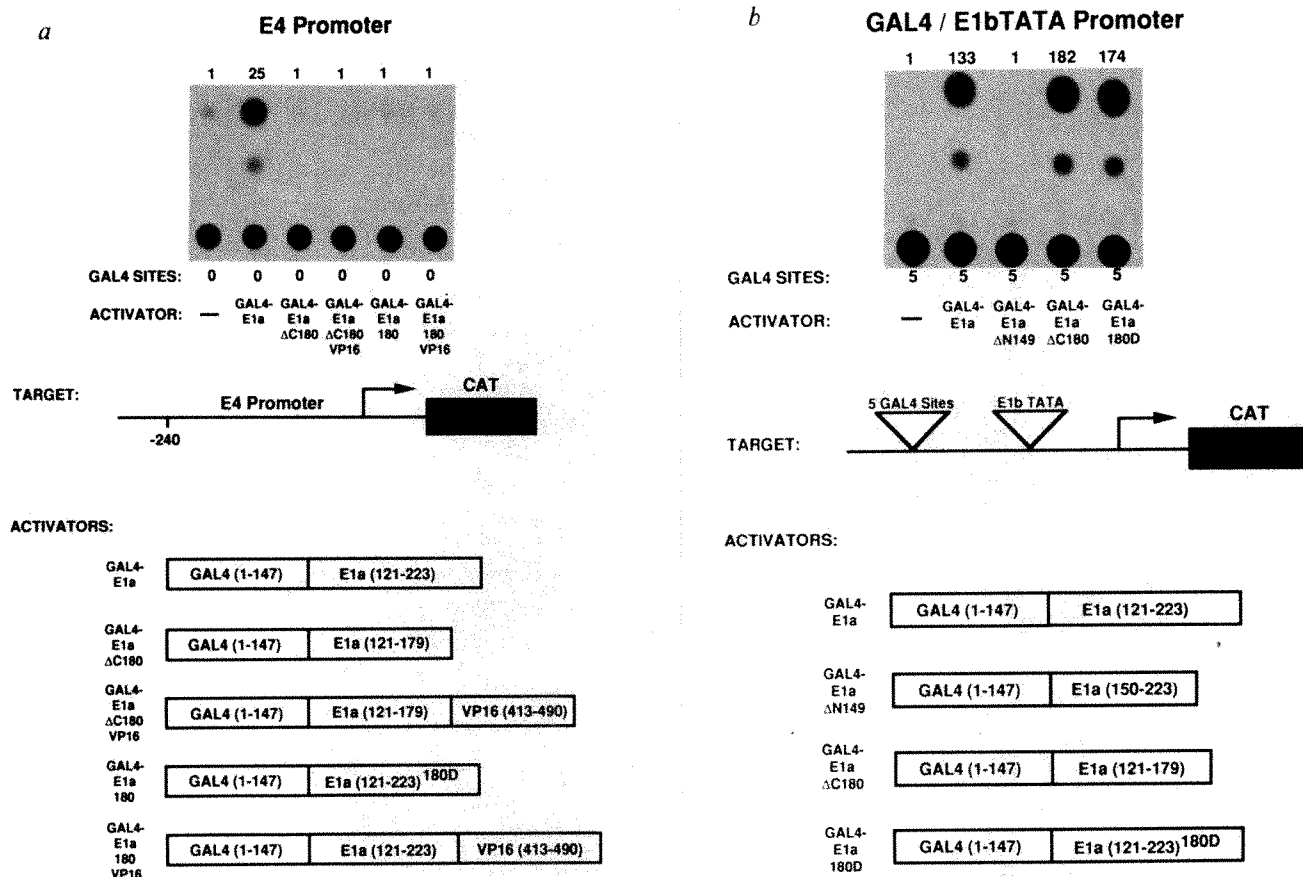

FIG. 5 The C terminus of E1a region 3 provides a promoter binding activity. A reporter CAT plasmid containing the E4 (a) or GAL4-E1bTATA (b) promoter was cotransfected with a plasmid encoding the activator indicated below each track. Relative CAT activity was quantitated and is indicated above each track.

METHODS. Transfections were as described in the Fig. 1 legend. Each activator is a derivative of GAL4-E1a described in the Fig. 1 legend. GAL4-E1aΔN149 is described in the Fig. 2 legend. GAL4-E1aΔC180 is E1a amino acids 121-179

fused to GAL4(1-147) and was created by a 3' *Bal*31 deletion of the *Clal*-*Xba*I fragment of the E1a 13S cDNA. GAL4-E1a180D contains a substitution at E1a amino acid 180 (Gly → Asp) and was constructed by replacing the *Clal*-*Xba*I fragment of GAL4-E1a with the *Clal*-*Xba*I fragment of the E1a activation mutant pH3G-13S-1098 (ref. 26). GAL4-E1aΔC180-VP16 and GAL4-E1a180D-VP16 contain the 78 C-terminal amino acids of the HSV1 protein fused in-frame to the C terminus of GAL4-E1aΔC180 and GAL4-E1a180D, respectively.

(Fig. 1a, GAL4-VP16). The only other sequences contained in GAL4-E1aΔN149 are E1a amino acids 150-223, suggesting that these E1a sequences provide a promoter-binding function. Below, we confirm this conclusion and further show that the sequences involved in promoter binding are required for E1a's natural activity.

Previous studies have shown that the C-terminal fragment of region 3 is important for wild-type E1a function<sup>24,26,28,30</sup>. The experiments in Fig. 5 indicate that the primary activity of this region is to bring the E1a activating region to the vicinity of its natural target promoters. Deletion of E1a amino acids 180-223, or substitution of amino acid 180, abolishes GAL4-E1a's ability to activate the E4 promoter, which lacks GAL4 sites (Fig. 5a, GAL4-E1aΔC180, GAL4-E1a180D; E4 promoter). The GAL4 DNA-binding domain restores the activity of these C-terminal mutants but only on a promoter that contains GAL4 sites (Fig. 5b, GAL4-E1aΔC180, GAL4-E1a180D; GAL4/E1bTATA promoter). Thus, the function of E1a amino acids 180-223 can be provided by the binding region of another activator.

The VP16 activating region, which restores the activity of region 3 N-terminal mutants, does not substitute for the C-terminal portion of region 3 (Fig. 5a, GAL4-E1aΔC180-VP16, GAL4-E1a180D-VP16). Conversely, the GAL4 DNA-binding domain, which restores the activity of region 3 C-terminal mutants, does not substitute for the N-terminal portion of region 3 (Fig. 5b, GAL4-E1aΔN149). Thus, the two ends of region 3 provide distinct activities, both of which are required for activation by wild-type E1a.

## Model

Taken together our results suggest that E1a functions naturally in the vicinity of the promoter. E1a contains both a promoter-binding region that directs E1a to its target promoters, and an activating region that functions when positioned at the promoter via the GAL4 DNA-binding domain or E1a's natural binding region (Fig. 6a). The activating and binding regions of cellular activators are modular, can be replaced by the corresponding region of an unrelated activator, and are functional independent of their position (reviewed in ref. 3). Similarly, we show that the N-terminal E1a activating region can be replaced by the VP16 activating region at the C-terminus, and the C-terminal E1a binding region can be replaced by the GAL4 DNA-binding domain at the N terminus. The activating regions of typical cellular activators are acidic (reviewed in ref. 3), and we note that the E1a activating region contains several acidic amino acids (Fig. 6c). The central portion of region 3 (amino acids 154-174), which contains a metal-binding domain<sup>46</sup>, is important for wild-type E1a activity<sup>30,46</sup>. Future experiments will determine if this domain is a component of the activating and/or the promoter-binding regions.

How is E1a targeted to the E4 and other viral early promoters? Our results indicate that E1a functions at the promoter, but there is no evidence that E1a binds to a specific DNA sequence (reviewed in ref. 17). It therefore seems probable that E1a's binding region recognizes a DNA-bound protein and not DNA. In this regard, E1a would resemble activating proteins such as

FIG. 6 Model of E1a action. *a*, Transcription activation by GAL4-E1a. A proposal for how GAL4-E1a interacts with target promoters that contain (right) or lack (left) GAL4-binding sites. GAL4-E1a protein is shown as a fusion of GAL4(1-147) and E1a. 'Binding' indicates the E1a promoter-binding region and shading indicates the E1a activating region. The unidentified component with which the E1a binding region interacts in the absence of GAL4 sites is shown by a question mark. *b*, Regions responsible for E1a activity. The structure of E1a 13S mRNA, which encodes the 289-amino acid protein, is shown on top. The intron removed by splicing is designated by a caret. The position of the 12S 5' splice site is indicated by a dotted line. The three conserved regions of the 289-amino acid E1a protein (box) are numbered 1, 2 and 3. The regions involved in activation are shown below. Four of the cysteines within the metal-binding region are shown. *c*, Amino-acid sequence shown to be involved in the E1a activating region. E1a amino acids 139 to 149 are shown. Negatively charged amino acids are stippled.

c-fos and HSV1 VP16, which interact with DNA-bound proteins and contribute additional activating regions<sup>4-10,45</sup>. One potential target protein is the cellular transcription factor ATF, which binds to multiple E1a-inducible adenoviral early promoters, including E4 (ref. 47).

If E1a functions at the promoter like a typical cellular activator, what accounts for its promiscuity? One possibility is that E1a's binding region recognizes more than one target protein. In fact, E1a is known to interact with multiple cellular proteins<sup>48,49</sup>. Perhaps E1a binds to some proteins, like ATF, avidly and to other cellular proteins with lower affinity. This could account for the variable effect of E1a on different pro-

motors<sup>17</sup>. In this regard, insertion of GAL4 sites greatly enhances activation of promoters that are otherwise weakly induced by GAL4-E1a, and modestly enhances activation of promoters that are otherwise efficiently induced by GAL4-E1a (Fig. 1; compare E4, MMTV and E1bTATA promoters). Alternatively, there may be additional mechanisms, unrelated to the one described here, by which E1a activates transcription.

In addition to adenovirus, other viruses such as pseudorabies virus<sup>50</sup>, bovine papilloma virus<sup>51</sup> and human T lymphotropic virus-1<sup>52</sup> encode proteins that activate transcription somewhat promiscuously. We speculate that these viral activators function in a similar way to E1a. □

# Bars within bars: a mechanism for fuelling active galactic nuclei

Isaac Shlosman\*, Juhan Frank†  
& Mitchell C. Begelman‡

Joint Institute for Laboratory Astrophysics, University of Colorado and  
National Bureau of Standards, Boulder, Colorado 80309, USA

ACTIVE galactic nuclei (AGNs) are usually thought to be powered by accretion onto a supermassive black hole (SBH)<sup>1,2</sup>. Their luminosities, which may exceed  $10^{46}$  erg s<sup>-1</sup>, require mass accretion rates of  $\geq 1 M_{\odot}$  yr<sup>-1</sup> for reasonable mass-to-energy conversion efficiencies. Although this quantity of fuel could be supplied by the interstellar medium of the host galaxy, it is not obvious how it could be transported from typical galactic radii,  $\sim 10$  kpc, down to the scale of the SBH,  $\leq 10$  pc. We propose here a mechanism, applicable to AGNs and nuclear starburst galaxies, which brings in gas from large to small scales by successive dynamical instabilities. On the large scale, a stellar bar sweeps the interstellar medium into a gaseous disk of a few hundred parsecs in radius. Under certain conditions, this disk can become unstable again, allowing material to flow inwards until turbulent viscous processes control angular-momentum transport. This flow pattern may feed viscosity-driven accretion flows around a SBH, or lead to the formation of a SBH if none was present initially.

If the accretion flow is disk-like and is driven by local viscosity, then the radial inflow time can be expressed in terms of the standard  $\alpha$  parameter<sup>3</sup>, which is defined as a suitably averaged ratio of viscous stress to pressure inside the disk. For a disk with shear induced by a point-mass potential, the viscosity-controlled radial inflow time,  $t_{\text{visc}}$ , is

$$t_{\text{visc}} = \alpha^{-1} (v_{\phi}/c_s)^2 t_{\text{dyn}} \approx 1.2 \times 10^9 \alpha^{-1} v_{\phi 2} T_2^{-1} R_{10} \text{ yr} \quad (1)$$

where  $100 v_{\phi 2}$  km s<sup>-1</sup> is the orbital speed,  $10 R_{10}$  pc is the radius,  $t_{\text{dyn}}$  is the dynamical time  $R/v_{\phi}$ ,  $c_s$  is the sound speed in the disk, and  $100 T_2$  K is the gas temperature<sup>4,5</sup>. An alternative viscosity formulation, obtained by setting the coefficient of kinematic viscosity to  $\nu = \alpha c_s H$ , where  $H$  is the disk thickness, gives identical results for a non-self-gravitating disk, but leads to a slower inflow rate when vertical self-gravity is important. Because of the effects of self-gravity and fragmentation<sup>4-7</sup>, the disk feeding an AGN may resemble a system of gas clouds rather than a quasi-continuous fluid. In this case, the efficiency of angular-momentum transfer depends on the cloud-cloud collision timescale,  $t_{\text{coll}}$ , and the value of the effective  $\alpha$  is of order  $t_{\text{dyn}}/t_{\text{coll}}$ . We expect  $\alpha$  to be  $\leq 1$  at the onset of fragmentation, and to become smaller if the clouds contract further. If fragmentation is somehow suppressed, higher effective values of  $\alpha$  may be possible<sup>8</sup>, but a consideration of realistic heating and cooling processes suggests that this does not lead to a significant enhancement of inflow<sup>4,5</sup>. In regions where the stellar potential dominates over the potential of the SBH, the shear is reduced and the viscous inflow time is prolonged. We conclude, therefore that standard viscous processes are too slow to be effective in collecting gas liberated in the main body of the host galaxy. This can be overcome either if the gas is generated close to the SBH or if gas liberated at larger distances is brought in towards the SBH by a mechanism other than subsonic turbulent viscosity. For example, a large-scale non-axisymmetric disturbance of the galaxy, such as a stellar bar, is capable of inducing global shocks, thereby driving the inflow of gas towards the

centre. The amount of H I in spirals is observed to lie in the range  $10^8$ – $10^{10} M_{\odot}$ , and molecular gas may be more abundant by a factor of ten. Both the total H I, CO and H<sub>2</sub> content and the ratio of molecular gas to H I are maximal for spiral galaxies of type Sb to Sbc<sup>9,10</sup>. There is certainly enough gas present in spirals to power the whole range of AGN activity, provided that this gas can be swept inwards from several kpc down to tens of pc in a short time.

It has been known for some time that barred spiral galaxies are associated with Seyfert galaxies. Adams<sup>11</sup> noticed that a large number of Seyferts are barred. The 12 objects in his highest-resolution class are all barred spirals at some level, or show inner rings thought to be generated by bar instabilities<sup>12</sup>. Apart from ten obvious SB and SAB galaxies, this class contains NGC1068 and Mk10, which are observed to be barred<sup>13-15</sup>. In the next resolution class, Adams found that two thirds of the galaxies are SB or have rings. The remaining third either have an "amorphous body" or are seen edge-on, or their observation was subject to instrumental errors.

In a survey of a sample of Seyfert galaxies, Simkin *et al.*<sup>16</sup> concluded that there was an excess of bars, rings and oval distortions among Seyferts with respect to their control sample. A recent survey based on CCD images of a volume- and luminosity-limited sample by MacKenty<sup>17</sup> shows that Seyfert galaxies "nearly always possess mechanisms for transporting material into their nuclei (for example, peculiar, tidally interacting or barred galaxies)". In other respects the host galaxies appear normal, having colours, magnitudes and disk parameters typical of their morphological class. Clearly, the simplest interpretation of these observations is that all Seyferts are barred at some level.

The large-scale stellar bar cannot, however, be solely responsible for the AGN phenomenon. First, about half of the spiral galaxies in the sky are barred or show oval distortions whereas only a few per cent of them host AGNs (but see ref. 18). Second, the gas inflow generated by a barred rotating potential does not extend down to scales at which turbulent viscosity could take over. Numerical studies of the response of a compressible fluid to an imposed oval distortion of the potential indicate that, in these systems, the gaseous component loses angular momentum in a pair of shocks, and flows towards the centre of the galaxy in about ten rotation periods<sup>19,20</sup>. Given the fractional deviation of the potential from axial symmetry,  $\Delta\Phi$ , we can estimate the radius at which the shocks weaken and the inflow ceases to be dynamically driven. We assume that  $\Delta\Phi \approx \epsilon v_{\phi}^2$ , where  $\epsilon$  is of the order of 0.1. The condition for  $\Delta\Phi$  to cause a shock in the gas can be expressed as<sup>21</sup>  $c_g < 0.5(\gamma+1)\epsilon v_{\phi}$ , where  $c_g$  is the sound speed in the gas and  $\gamma$  is its adiabatic index. If the inner parts of the galaxy rotate as a solid body within a radius  $R_i$ , shocks will not be present within a radius  $R_d$  given by  $R_d = 2R_i/(\gamma+1)\epsilon M$ , where  $M$  is the Mach number ( $v/c_g$ ) of the flow at  $R_i$  and we have assumed  $c_g \ll v_{\phi}$ . Numerical simulations show that the gas can be swept up into a ring if inner Lindblad resonances (ILRs) are present, yielding a ring-like configuration of H II regions. If the bar distortion is strong, however, the positions of the ILRs cannot be calculated using the circular velocity curve<sup>22</sup>.

In summary, the gaseous inflow in a barred potential slows down at a radius  $R_d$ . We shall assume, for simplicity, that the net effect of a stellar bar on the gaseous component of the host galaxy is to sweep it into a disk with radial scale  $R_d \approx 0.1 R_b$ , where  $R_b$  is the radius of the bar. At  $R_d$ , viscous processes are still too slow to drive inflow. We propose instead that the gas which accumulates in the central kpc or so, as a consequence of the inflow in the stellar bar, forms a disk which, under certain conditions, becomes again dynamically unstable to form a gaseous bar. We derive a condition for this secondary instability in the context of a simple model, and argue that the resulting inflow can extend all the way into the centre of the galaxy, that is, to the inner  $\sim 10$  pc or so.

No single criterion is known for global stability of self-gravi-

tating disks (gaseous or stellar) encompassing all possible disk models<sup>22,23</sup>. However, the stability of a large variety of disk models can be described by applying the semi-empirical criterion proposed by Ostriker and Peebles<sup>24</sup>, which is known to have a theoretical analogue for Maclaurin ellipsoids. A sufficient condition for instability is given by  $t = T_{\text{rot}}/|W| \geq t_{\text{crit}}$ , where  $T_{\text{rot}}$  is the kinetic energy of rotation of the disk,  $W$  is the gravitational energy of the system and  $t_{\text{crit}}$  is the maximum value of  $t$  required for stability. This criterion seems to apply to gaseous thin disks, which have  $t_{\text{crit}} \approx 0.14$  for secular instability and  $t_{\text{crit}} \approx 0.26$  for dynamical instability<sup>25,26</sup>. We model the system after the bar has brought the gas within the radius  $R_d$  in terms of three components: a cool gaseous disk having a Kuzmin density distribution with radial scale  $a$ ; a stellar disk having a similar density distribution but with a larger radial scale  $b$ ; and a Plummer-model halo, also with radial scale  $b$  (see, for example, ref. 23). Let the total mass of the system be  $M$ , a fraction  $g$  of which is in the gaseous disk and a fraction  $s$  in the stellar disk. The halo therefore contains a mass  $(1 - g - s)M$ . This particular choice of model is motivated by the fact that  $t$  can be evaluated analytically, but the conclusions drawn from it are expected to be at least qualitatively correct in a more general context.

We treat the potential of the stellar component as axisymmetric and fixed, and therefore include in the calculation of  $t$  only the kinetic energy of the gaseous disk:

$$T_{\text{rot}} = \frac{gf^2GM^2}{8a} \left[ g + \frac{4(1-g)}{(1+\beta)^2} \right] \quad (2)$$

where we have assumed that the disk rotates at every radius with a fraction  $f$  of the local circular speed for equilibrium ( $f=1$  indicates full rotational support), and have introduced  $\beta \equiv b/a$ , the ratio of length scales of the fixed stellar component to the gaseous component. From equation (2) and the expression for the potential energy,

$$|W| = \frac{GM^2}{4a} \left[ g^2 + \frac{4g(1-g)}{1+\beta} + \frac{s(2-2g-s)}{\beta} + \frac{3\pi}{8\beta} (1-s-g)^2 \right] \quad (3)$$

one can obtain an expression for  $t$  in terms of the mass fractions in the various components and the radial-scale ratio  $\beta$ . The physically interesting question is: given a certain gas fraction, by how much must the gas disk shrink radially in order to become unstable? A rough answer to this question can be obtained by setting  $t$  equal to  $t_{\text{crit}}$  and solving for  $\beta$ . In the limit  $g \ll 1$ , we find that the gaseous disk is unstable ( $t > t_{\text{crit}}$ ) if

$$\beta > \frac{2t_{\text{crit}}(1-h^2+3\pi h^2/8)}{g^2(f^2-2t_{\text{crit}})} \quad (4)$$

where  $h \equiv 1 - g - s$  is the halo mass fraction. The r.h.s. of eq. (4) is not very sensitive to the value of  $h$ , and equation (4) holds to better than 10% for  $g \leq 0.3$ , when compared with the exact evaluation of the Ostriker-Peebles criterion. Any effects of non-axisymmetry will probably enhance the instability.

Two aspects of equation (4) are worth mentioning: (1) for a given  $f$  and  $h$ ,  $\beta$  varies inversely with the gas fraction squared, and (2) the disk must be cold,  $f > \sqrt{2t_{\text{crit}}}$  for it ever to become unstable. This places stringent limits on the proposed mechanism. For example, in a cold disk with  $f=1$ ,  $h \approx 0.5$  and  $t_{\text{crit}} = 0.14$ ,  $\beta$  must be  $> 0.4/g^2$  for instability. If  $\beta=1$  initially and  $g \approx 0.2$ , then a reduction in size of the gas disk by a factor of ten would make it susceptible to global instabilities. It is important to note that the value of  $t_{\text{crit}} = 0.14$  used above corresponds to dynamical instability of stellar (collisionless) disks, but to only secular instability of gaseous disks. This is because gaseous disks have fewer degrees of freedom than stellar disks. Secular instability of a gaseous disk would occur on the viscous inflow time, and would therefore be too slow to be of interest. Dynamical instability of a smooth gaseous disk would require  $t_{\text{crit}} = 0.26$ , corresponding either to contraction by an additional factor of 2-3,

or to increase in  $g$  by a factor of about two. However, it is likely that the self-gravitating gaseous disk will be highly inhomogeneous, consisting of clouds which fill a rather small fraction of the volume<sup>5</sup>. If the collision frequency of clouds is small relative to the orbital frequency, the system will behave more like a stellar disk than a gaseous disk, and a lower value of  $t_{\text{crit}}$  will apply. Gravitational coupling of the gaseous disk to the stellar disk may also contribute to the instability<sup>5,27</sup>.

Therefore, we have established that a large-scale stellar bar sweeping the gas inward yields a disk, which can become unstable, if it is not too hot, and can feed a viscosity-driven flow. The unstable configuration is likely to resemble a bar-driven spiral<sup>25</sup>, which will transfer angular momentum outwards, leading to further contraction. At the same time, the velocity dispersion of inhomogeneities will tend to increase, but this energy will be dissipated through cloud-cloud collisions. To the extent that the system does not form stars, the inevitable consequence of sinking of the gaseous system towards the centre of the stellar system is that  $t$  will grow, and the gaseous system will become increasingly unstable. The degree to which the system forms stars before the gas reaches the centre must, in this model, determine whether the principal form of activity is a starburst or an AGN. The above argument implies that galaxies with a gas content of less than 10% will not display a bar within a bar and are therefore candidates for the generation of a starburst but not of a powerful AGN.

The process is not necessarily restricted to spirals. Elliptical galaxies are to some extent also supported by rotation. Material that is released at radii of a few kpc, and which is only 1% rotationally supported, would go into keplerian orbit at about one tenth of its original distance from the centre. Turbulent viscosity would still be insufficient to drive inflow, and the formation of a gaseous bar might occur even in this case.

Thus, a large-scale bar is a necessary but not sufficient condition for strong nuclear activity if the host is a spiral galaxy. Another stage of dynamical instability, which occurs in the gaseous disk that accumulates in the centre under the influence of the stellar bar, is required to feed an accretion disk at smaller scales, that is, such a process requires gaseous bars within stellar bars. A similar but tidally induced process was found in numerical simulations (L. Hernquist, preprint). Any process that suppresses this second stage of instability will prevent formation of the SBH and/or its subsequent fuelling, and is likely to lead to nuclear star formation or to low-level activity. This view is supported by recent evidence that most or perhaps all starbursts are barred<sup>28</sup>. The majority of spirals avoids becoming a conspicuous AGN or starburst. The most probable causes for this are relatively low gas content of the host, inefficiency of the stellar bar in sweeping all of the gas in, and the presence of ILRs.

The fact that activity seems to occur preferentially in intermediate morphological classes can be simply explained in terms of the relative abundance of gas-rich galaxies among those morphological types<sup>9,10</sup>. Additional factors, such as the length of the bar relative to the photometric galactic radius, may influence the correlation between activity and morphological type. It is plausible that nuclear activity in some galaxies may be suppressed at present because the SBH (or the nuclear starburst) has exhausted the available mass supply and must wait for new material to be brought in from large scales. The duration of the active phase of an AGN would be of the order of a few  $t_{\text{dyn}}$  at the bar radius, whereas the gas would be replenished only on the stellar-evolution timescale or on the timescale for capture of extragalactic clouds.

An important prediction of this model is that dynamical instabilities on scales of  $\sim 100$  pc must be present in the central regions of active galaxies, including ellipticals (such as powerful radio galaxies). Perhaps some evidence of the processes discussed here can be found in the Sérsic-Pastoriza galaxies, whose nuclei have been long recognized as unusually bright and disturbed<sup>29</sup>. All of these galaxies are barred at some level and some

of them are well-known today to be Seyferts and starbursts. More high-resolution optical and infrared observations of these objects and H I and CO observations of the innermost regions of moderately distant AGN are desirable.

We have not discussed the effects of environment on Seyferts and starbursts. The passage of a close companion may induce a stellar bar, but this may not be necessary for their production, as isolated galaxies may host bars which are relics from galaxy formation, or which have been generated spontaneously as a result of infall. □

## A global assessment of natural sources of atmospheric trace metals

Jerome O. Nriagu

National Water Research Institute, Box 5050, Burlington, Ontario L7R 4A6, Canada

A PROPER inventory of atmospheric emissions from natural sources is basic to our understanding of the atmospheric cycle of the trace metals (and metalloids), and is also needed for assessing the extent of regional and global pollution by toxic metals<sup>1</sup>. It is generally presumed that the principal natural sources of trace metals in the atmosphere are wind-borne soil particles, volcanoes, seasalt spray and wild forest fires<sup>2–6</sup>. Recent studies have shown, however, that particulate organic matter is the dominant component of atmospheric aerosols in non-urban areas<sup>7–10</sup> and that over 60% of the airborne trace metals in forested regions can be attributed to aerosols of biogenic origin<sup>11,12</sup>. Here I estimate that biogenic sources can account for 30–50% of the global baseline emissions of trace metals. For most of the toxic metals, the natural fluxes are small compared with emissions from industrial activities, implying that mankind has become the key agent in the global atmospheric cycle of trace metals and metalloids.

In compiling the emission factors used in the calculations (Table 1), the most recent data have been used; for older data, the lowest reported concentrations have been preferred. For

enrichment factors, a range of values<sup>1</sup>, rather than a single value, has been used. A range in the flux of material from each source has also been employed so as to assess the errors inherent in the reported emission intensities of trace metals.

The episodic nature of volcanic emissions makes it difficult to derive trace-metal emission rates using the enrichment-factor strategy<sup>12,13</sup>. There have been numerous studies, however, of the release of sulphur and trace metals from volcanoes and fumaroles, and a number of authors have estimated the outputs of trace metals by normalizing the metal release to the sulphur flux from this source<sup>15</sup>. I have adopted such an approach here, using a global volcanic sulphur flux of  $(15\text{--}50) \times 10^{12} \text{ g yr}^{-1}$  (refs 15, 16) and metal-to-sulphur ratios derived from published data<sup>13–17</sup>.

The release of large quantities of volatile non-methane hydrocarbons (NMHC) is well documented, particularly in forested areas<sup>18–20</sup>. For example, the average emission rates for NMHCs in the forested areas of the United States range from 450 to  $1,712 \mu\text{g m}^{-2} \text{ h}^{-1}$  (ref. 18). Biogenic emissions of isoprene and terpenes in the Amazon rain-forests have been estimated as 233 and  $1,040 \mu\text{g m}^{-2} \text{ h}^{-1}$  respectively<sup>19</sup>. Rasmussen and Khalil<sup>20</sup> have calculated the global atmospheric flux of isoprene to be  $450 \times 10^{12} \text{ g yr}^{-1}$ , and the combined releases of isoprene and terpenes have been suggested<sup>19</sup> to be equivalent to ~0.7% of the net global primary production. Thus the NMHC flux of  $100\text{--}500 \mu\text{g m}^{-2} \text{ h}^{-1}$  used here is clearly a conservative figure. Terpenes and isoprene, the two dominant components of NMHCs, are known to form strong complexes with many trace metals<sup>21</sup>, and thus should play a part in the transfer of metals to the atmosphere. As far as I know, however, the NMHCs have not been analysed for trace metals, so that the emission factors listed in Table 1 are subject to a large uncertainty. They are based on reported flux measurements and the concentrations of methylated compounds of Hg, As, Pb and Se in the atmosphere<sup>6,14,24</sup>. For the other elements, the emission factors are based on metal concentrations in the surface organic microlayers of aquatic ecosystems<sup>22,23</sup>.

The average concentration of particulate organic carbon (POC; derived from organic matter which is the dominant component of atmospheric aerosols) in the Amazon rain-forests has been reported<sup>9</sup> to be  $8.9 \mu\text{g C m}^{-3}$  in the mixed layer and  $2.6 \mu\text{g C m}^{-3}$  in the free troposphere. These reported POC concentrations in forest ecosystems are considerably higher than the mean value of  $0.06 \mu\text{g C m}^{-3}$  in the marine atmosphere of the Southern Hemisphere<sup>44</sup>. The carbon isotope composition suggests, however, that most of the marine POC is also derived from natural land-based sources<sup>44</sup>. The annual flux of particulate organic matter (POM) to the atmosphere,  $Q$ , can be estimated from

$$Q = V \times B \times 2.2 \times (3\text{--}6) \times 10^{13}$$

where  $V$ , the total deposition velocity of the aerosols, is estimated to be  $1.0 \text{ cm s}^{-1}$  (ref. 44), and  $b$ , the average POC concentration, is  $3\text{--}9 \mu\text{g m}^{-3}$ . The figure of 2.2 is used to relate organic carbon to organic matter<sup>47</sup>, and the forested area is believed to be  $(3\text{--}6) \times 10^{13} \text{ m}^2$  (ref. 51). These values yield a global atmospheric POM flux of about  $(1\text{--}5) \times 10^{14} \text{ g yr}^{-1}$ . The POM flux used here is thus higher than the value of  $27 \times 10^{12} \text{ g yr}^{-1}$  reported recently by Cachier *et al.*<sup>44</sup>. The global flux of material from the other non-biogenic sources are summarized in Table 1.

There is a wide range in the estimated total emission of each metal from any given source (Table 1), reflecting the large dispersion in the emission factors used and in the published estimates of the mass flux from individual sources. There are significant gaps in the data, demonstrating the need for further study of the role of biological processes in the emission of trace metals. The proposed limits on the fluxes of metals from each source serve to indicate that current data are sufficient for only order-of-magnitude estimates of the global emission intensities. In view of this, the central (or median) values of the ranges

¶¶ Based on trace-metal concentrations in volcanic emanations reported in refs 5, 13, 15–17 and 44.

\*\* Quantity of forest biomass consumed by wild fires derived from the data given in refs 45–47.

†† Derived from the trace-metal concentrations in land plants<sup>4,13</sup> and assuming burning yields of 30% for Mn and Cr, 50% for Pb, Co, Cd, Mo, Sb, Cu and Zn, and 70% for Se, Hg, V and As (refs 46, 49).

‡‡ See text.

§§ Trace-metal concentrations in land plants, which are used to derive the emission factors in††.

||| The average emission of volatile non-methane natural hydrocarbons (NMHC) in the United States has been estimated to be 450, 884 and 1,712  $\mu\text{g m}^{-2} \text{h}^{-1}$ , respectively (refs 25–27). My calculation is based on NMHC flux of only (100–500)  $\mu\text{g m}^{-2} \text{h}^{-1}$  from (3–6)  $\times 10^{13} \text{ m}^2$  of forested area<sup>45,50</sup>.

¶¶ The data listed for As, Hg and Se are based on published measurements of volatilization rates (for review see, for example, refs 3, 14, 22, 23, 30, 31). The emission factors reported for the other metals are based on their concentrations in surface organic microlayers.

### I have assumed that the flux of volatile NMHCs from the 170  $\times 10^{12} \text{ m}^2$  of coastal shelf and upwelling areas of the ocean<sup>51</sup> is 50–200  $\mu\text{g m}^{-2} \text{h}^{-1}$ .

given should be used in preference to the mean values, used by other authors.

Based on these data, my inventories suggest that biogenic sources can account, on average, for over 50% of the Se, Hg and Mo, and 30–50% of the As, Cd, Cu, Mn, Pb and Zn, released annually to the atmosphere from natural sources (Table 1). This important source of metals in the atmosphere has been either ignored or badly underestimated in most of the previously published inventories of trace-metal emissions from natural sources (for example, refs 2–6). This large estimated biogenic flux is consistent with recent reports<sup>10,11</sup> that the vegetation accounts for up to 90% of the airborne trace metals in the Amazon Basin. Biologically mediated volatilization processes can account for 30–50% of the total Hg, As and Se emitted annually, whereas the other metals are primarily associated with pollens, spores, waxes, leaf and needle fragments, fungi, algae and so on.

Records in polar ice layers<sup>26</sup> indicate that major volcanic eruptions often result in massive outputs which dominate the global atmospheric cycle of trace metals. My global inventory suggests that volcanic emanations can account for 40–50% of the Cd and Hg and 20–40% of the As, Cr, Cu, Ni, Pb and Sb emitted annually (Table 1). The data for volcanogenic sources (Table 1) are consistent with those reported recently by Lambert *et al.*<sup>15</sup>, who used the release of <sup>210</sup>Pb to normalize the SO<sub>2</sub> and trace-metal outputs. Patterson and Settle<sup>5</sup>, however, estimated the annual volcanic flux of Pb to be only 0.5  $\times 10^{12}$  g (corrected from the value of 1.2  $\times 10^{12}$  g published by these authors), a

value which is lower than the median value but which falls within the range shown in Table 1. The sulphur flux of (15–50)  $\times 10^{12}$  g used here presumably includes sulphur (and hence is accompanied by trace metals) from both eruptive and non-eruptive activity; fumarolic sulphur emission alone has been estimated to be (15–27)  $\times 10^{12}$  g yr $^{-1}$  (ref. 27).

With the exception of As (14%) and Sb (16%), seasalt aerosols seem to account for <10% of atmospheric trace metals from natural sources. The seasalt emission rates reported by Wiesel *et al.*<sup>28</sup> generally fall towards the upper end of the ranges in Table 1. At present, it is impossible to differentiate between biogenic and (seasalt) spray origins of trace metals in the marine atmosphere, although my inventory tends to favour biological processes as the main contributor. Soil-derived dusts can account for over 50% of the total Cr, Mn and V emissions, as expected. This source may also account for 20–30% of the Cu, Mo, Ni, Pb, Sb and Zn, but <10% of the Hg and Se released annually to the atmosphere. By ignoring biogenic outputs, previous estimates have generally overestimated the importance of resuspended soil particles in the atmospheric trace-metal budget.

The data in Table 1 pertain to emissions in recent years and therefore include some recycled anthropogenic metals. For some metals, the emission rates in prehistoric times were conceivably lower than those calculated today. Biological processing of trace metals dispersed in the environment by human activities is well documented (see, for example, refs 14, 24, 31, 33, 39). It is impossible, however, to use the available information to quantify the contribution of recycled material to the total flux of any of

TABLE 2 Natural versus anthropogenic emissions of trace metals to the atmosphere in 1983

Trace metal	Anthropogenic source	Natural source	Total emission	Natural/total emissions*

\* Median values only.

the trace metals and metalloids.

The total outputs listed in Table 1 do not agree with the inventories of natural source emissions published by other authors<sup>2,4,6</sup>. Because of refinement of the biogenic component, the data given here are generally higher than those given in my previous report<sup>2,9</sup>. In spite of discrepancies in source intensities, the calculated As flux is in good agreement with the value of  $7.8 \times 10^9 \text{ g yr}^{-1}$  reported by Walsh *et al.*<sup>2</sup>, but is less than half of that reported more recently by Chivers and Peterson<sup>30</sup>. The total annual Hg flux of  $(4\text{--}5) \times 10^9 \text{ g}$  reported by Fitzgerald<sup>31</sup> and the Se flux of  $(6\text{--}13) \times 10^9 \text{ g}$  reported by Mosher and Duce<sup>14</sup> are in good agreement with the inventories for these two elements in Table 1.

A comparison of the median values of the worldwide emissions of trace metals from natural and anthropogenic sources suggests that industrial emissions of Pb, Cd and Zn exceed the flux from natural sources by factors of 18, 5 and 3 respectively (see Table 2). Industrial discharges are apparently exercising a profound influence on the atmospheric cycles of these three toxic metals. For As, Hg, Ni, Sb and V, the contributions from anthropogenic sources may exceed those from natural sources by 100–200%. Thus it seems that mankind has become the key agent in the global atmospheric cycle of the toxic metals and metalloids. □

UNTIL recently, all known high- $T_c$  superconductors involved conduction by holes; the doping of holes into the parent compound, for example by the substitution of  $\text{Sr}^{2+}$  or  $\text{Ba}^{2+}$  for  $\text{La}^{3+}$  in  $\text{La}_2\text{CuO}_{4-y}$ , results in a metallic state whose electronic ground state is superconducting. Recently, Tokura *et al.*<sup>1</sup> have discovered a series of superconducting copper oxides of general formula  $\text{Ln}_{2-x}\text{Ce}_x\text{CuO}_{4-y}$  (where Ln represents Pr, Nd, Sm), with transition temperatures as high as  $T_c \approx 24 \text{ K}$ , in which the charge carriers are electrons. These compounds have the  $\text{Nd}_2\text{CuO}_{4-y}$  structure, which is similar to that of  $\text{La}_2\text{CuO}_{4-y}$  except for a different arrangement of the oxygen atoms that results in the absence of Cu–O octahedra. Superconductivity is achieved by doping  $\text{Ce}^{4+}$  for  $\text{Ln}^{3+}$  and making the samples oxygen-deficient. Here we show, using muon spin rotation, that the parent compounds  $\text{Ln}_2\text{CuO}_{4-y}$  of these electron-superconductors exhibit static magnetic order below 300 K, which is similar to that observed in the parent compounds of hole-superconductors. In addition, fairly random static magnetic order has been observed in the non-superconducting material  $\text{Nd}_{1.90}\text{Ce}_{0.10}\text{CuO}_{4-y}$  below about 240 K, but no detectable static magnetic order was observed above 4 K in a superconducting sample  $\text{Nd}_{1.8}\text{Ce}_{0.16}\text{CuO}_{4-y}$  (with a  $T_c$  of 24 K). Hence, electron

doping seems not to fully destroy the magnetic order until the material becomes superconducting. The observation of static magnetic order in these new systems demonstrates that the electronic properties of these copper oxide planar systems are at least partially symmetric with respect to electron and hole doping.

The technique of positive muon spin rotation<sup>2</sup> ( $\mu$ SR) has been applied extensively to the study of high- $T_c$  superconductors and related materials<sup>3-8</sup>. In solids, the positive muon serves as a sensitive probe of the internal magnetic fields at interstitial sites(s), where the muon resides. In an antiferromagnet one observes one or more discrete oscillation frequencies in zero applied field<sup>9-11</sup>, which are independent of the relative orientation of the local field with respect to the initial polarization and are thus the same for a powder and a crystal. In a disordered magnetic system such as a spin glass, in which there is a broad distribution of local-field magnitudes at the muon site(s), the coherence of the muon spins is quickly lost, and this appears as a rapid depolarization of the muon polarization<sup>12</sup>.

The application of a weak external transverse magnetic field allows one to determine the volume fraction of the sample that

is magnetically ordered. Muons that reside in sites at which there is an appreciable internal magnetic field ( $\sim 30$  G or greater) are quickly depolarized, whereas those in sites with no local ordered field precess in the applied external field<sup>11</sup>. Thus the fraction of the muon polarization that precesses coherently corresponds to the volume fraction of the sample that has no appreciable static moment.

The pure parent compounds were prepared at DuPont Experimental Station by solid-state reactions of the rare-earth oxides ( $\text{Nd}_2\text{O}_3$ ,  $\text{Pr}_2\text{O}_3$ ,  $\text{Sm}_2\text{O}_3$ ) with  $\text{CuO}$  at  $1,000$ – $1,100^\circ\text{C}$ , as described elsewhere (J. Gopalkrishnan *et al.*, preprint). X-ray diffraction indicated that the samples were substantially single-phase; powder neutron diffraction revealed the crystal structure to be that of  $\text{Nd}_2\text{CuO}_4$  (described in ref. 1).

The experiments were performed at the M20 surface muon channel at TRIUMF which provides a beam of  $\sim 100\%$  spin-polarized positive muons. Figure 1 shows the zero-field muon polarization at low temperature in  $\text{Nd}_2\text{CuO}_{4-y}$ ,  $\text{Pr}_2\text{CuO}_{4-y}$  and  $\text{Sm}_2\text{CuO}_{4-y}$ . Over much of the temperature range the coherence of the muon spins is lost after a few periods of oscillation. This

FIG. 1 Zero-field  $\mu$ SR spectra for  $\text{Nd}_2\text{CuO}_{4-y}$ ,  $\text{Pr}_2\text{CuO}_{4-y}$  and  $\text{Sm}_2\text{CuO}_{4-y}$  below the ordering temperature.

FIG. 2 Temperature dependence of the disordered (paramagnetic) volume fraction in  $\text{Nd}_2\text{CuO}_{4-y}$  and  $\text{Pr}_2\text{CuO}_{4-y}$ .

FIG. 3 Temperature dependence of the square root of the muon spin relaxation second moment, measured in zero magnetic field for  $\text{Nd}_2\text{CuO}_{4-y}$  and  $\text{Pr}_2\text{CuO}_{4-y}$ .

FIG. 4 Zero-field  $\mu$ SR spectra for reduced samples of non-superconducting  $\text{Nd}_2\text{CuO}_{4-y}$  and  $\text{Nd}_{1.90}\text{Ce}_{0.10}\text{CuO}_{4-y}$ , and superconducting  $\text{Nd}_{1.84}\text{Ce}_{0.16}\text{CuO}_{4-y}$ .

indicates that the width of the local distribution at the muon site(s) is of the same order of magnitude as the average field. At some temperatures, however, longer-lived precession is clearly visible, indicating that at least short-range magnetic order (rather than mere spin freezing) does occur in these materials. Figure 2 shows the paramagnetic or non-ordered sample volume fraction as a function of temperature for  $\text{Nd}_2\text{CuO}_{4-y}$  and  $\text{Pr}_2\text{CuO}_{4-y}$ .

We have parameterized the muon relaxation function as  $\exp(-\frac{1}{2}\sigma^2 t^2) \cos(\omega t)$ , corresponding to a gaussian distribution of local fields centred about  $\omega/\gamma_\mu$ . The fitted frequency  $\omega$  and the relaxation rate  $\sigma$  are highly correlated when there is such rapid relaxation, so that we then extract the initial second moment of the spin relaxation, given by  $M_2 = \sigma^2 + \omega^2$ . The square root of the second moment is plotted as a function of temperature in Fig. 3 for  $\text{Nd}_2\text{CuO}_{4-y}$  and  $\text{Pr}_2\text{CuO}_{4-y}$ . The low-temperature values of  $M_2$  are consistent with values reported for  $\text{La}_2\text{CuO}_{4-y}$  (refs 9, 10). The similarity in size of the ordered moment leads us to conclude that it is the copper-atom spins that are ordered (as in  $\text{La}_2\text{CuO}_{4-y}$ ), because if the rare-earth atoms were ordered, the ordered moment would be much larger. In a neutron scattering experiment on an essentially similar sample of  $\text{Pr}_2\text{CuO}_{4-y}$  below  $T = 300$  K, Cox *et al.* (personal communication) have observed Bragg scattering that is consistent with antiferromagnetic ordering of copper spins, and an earlier electron paramagnetic resonance study<sup>13</sup> found indications of antiferromagnetic order of copper spins in the  $\text{Ln}_2\text{CuO}_{4-y}$  materials.

The temperature at which the spins freeze (that is, at which a large static component of the local moment develops) is  $\sim 300$  K for all three compounds. In each of these materials, however, the degree of randomness in the magnetic order exhibits a complex temperature dependence, which will be discussed fully elsewhere.

To study the effects of carrier doping on the magnetic behaviour of these materials, we studied three specimens in the series  $\text{Nd}_{2-x}\text{Ce}_x\text{CuO}_{4-y}$ : the undoped parent compound  $\text{Nd}_2\text{CuO}_{4-y}$ , a partially doped, non-superconducting sample  $\text{Nd}_{1.90}\text{Ce}_{0.10}\text{CuO}_{4-y}$  and a more fully doped superconducting sample  $\text{Nd}_{1.84}\text{Ce}_{0.16}\text{CuO}_{4-y}$ , for which  $T_c = 24$  K. All three samples, which were prepared at the University of Tokyo<sup>1</sup>, were reduced at  $900^\circ\text{C}$  under an  $\text{Ar}/\text{O}_2$  atmosphere with a low oxygen partial pressure, making them oxygen-deficient ( $y > 0$ ). Representative  $\mu\text{SR}$  spectra in zero applied field are shown in Fig. 4.

In both non-superconducting samples, static internal fields were observed, indicating some sort of magnetic order or spin freezing. The presence of coherent oscillations (Fig. 4) indicates that more uniform magnetic order occurs in the oxygen-deficient  $\text{Nd}_2\text{CuO}_{4-y}$  than in the more fully oxygenated sample shown in Fig. 1. The temperature dependence of this uniformity of order is, however, also complex in this sample. The onset temperature of spin-freezing in the  $x = 0.10$  Ce-doped sample was reduced to  $T_N \approx 240$  K, and the complete sample volume was ordered or frozen by  $T = 150$  K. The magnitude of the static moment at low temperature was approximately the same as that of the parent compound  $\text{Nd}_2\text{CuO}_{4-y}$ . The presence of static magnetic order at such a high temperature in a material with substantial doping contrasts with the  $\text{La}_{2-x}\text{Sr}_x\text{CuO}_{4-y}$  system: magnetic order is lost above about 5 K in  $\text{La}_{1.92}\text{Sr}_{0.08}\text{CuO}_{4-y}$ , and at lower temperatures for higher Sr concentrations<sup>14</sup>.

The superconducting  $\text{Nd}_{1.84}\text{Ce}_{0.16}\text{CuO}_{4-y}$  sample exhibited no detectable static magnetic order above 4 K. The zero-field relaxation increased somewhat below 60 K (Fig. 4) but was still much less than that seen in non-superconducting samples.

In all of the non-superconducting specimens studied, we observe a more random and complicated magnetic behaviour as a function of temperature than the simple antiferromagnetic ordering observed in the  $\text{La}_2\text{CuO}_{4-y}$  system<sup>9,10</sup>. This behaviour may be due to changes in the ordered spin structure with

temperature, resulting in changing magnetic environments for the muon site(s). An orthorhombic distortion in the  $\text{La}_2\text{CuO}_{4-y}$  system stabilizes the magnetic structure of the body-centred copper atoms. In the Ce-doped materials, however, the structure remains tetragonal over the full temperature range and thus the body-centred copper atoms do not have a specific energetically preferred orientation. As there are two equivalent possible orientations of the copper-atom moments, a large degree of randomness in the magnetic order might be expected. Neutron-scattering measurements on single-crystal specimens are necessary to resolve this point, because  $\mu\text{SR}$  by itself cannot easily determine the ordered spin structure or the range of the order, as the muons are affected mainly by the nuclei of their nearest neighbours.

Thus the magnetic behaviour of the parent compounds of the electron-superconductors is rather similar to that of the corresponding hole-superconductors, in that ordering occurs at roughly the same temperature with an equivalent static moment. In view of the proposed link between magnetic and superconducting properties in these materials, such information may be of great importance in determining how, if at all, the mechanisms for superconductivity differ for the two classes of compound.  $\square$

## Wavelet analysis of turbulence reveals the multifractal nature of the Richardson cascade

F. Argoul\*, A. Arnéodo\*, G. Grasseau\*, Y. Gagne†, E. J. Hopfinger† & U. Frisch‡

‡ Observatoire de Nice, Unité Associée CNRS, BP 139, 06003 Nice Cedex, France

THE central problem of fully developed turbulence is the energy-cascading process. It has resisted all attempts at a full physical understanding or mathematical formulation. The main reasons for this failure are related to the large hierarchy of scales involved, the highly nonlinear character inherent in the Navier–Stokes equations, and the spatial intermittency of the dynamically active regions. Richardson<sup>1</sup> has described the interplay between large and small scales with the words ‘Big whirls have little whirls which feed on their velocity ... and so on to viscosity’, and the phenomenon so described is known as the Richardson cascade. This local interplay also forms the basis of a theory by Kolmogorov<sup>2</sup>. It was later realized that the cascade ought to be intermittent, and Mandelbrot<sup>3</sup> has given a fractal description of the intermittency of the fine structure. A particular case that emphasizes the dynamical aspect of the fractal models is the  $\beta$ -model<sup>4</sup>, in which the flux of energy is transferred to only a fixed

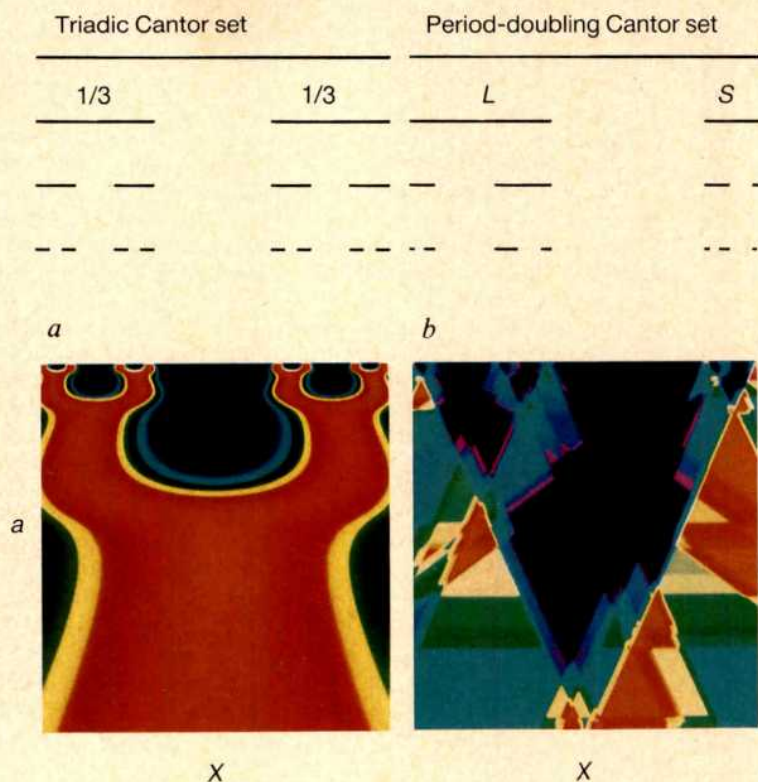

FIG. 1 Wavelet analysis of Cantor sets<sup>9,15</sup>. Coordinates correspond to space ( $x$ ) and scale ( $a$ ); both are linear (small scales at the top). The intensity of the wavelet transform is colour-coded according to the natural light spectrum from black (low intensity) ( $T_g \leq 0$ ) to red ( $\max(T_g) > 0$ ) on each line  $a = \text{constant}$ . *a*, Uniform triadic Cantor set analysed using a 'Mexican hat' wavelet:  $g(x) = (1 - x^2) e^{-x^2/2}$ ;  $x \in [0, 1]$ ,  $a \in [2^{-9}, 2^0]$ . *b*, Period-doubling Cantor set analysed using 'French hat' wavelets:  $g(x) = 1(|x| < 1)$ ,  $-1/2(1 \leq |x| \leq 3)$ ,  $0(|x| > 3)$ ;  $x \in [-0.40115, \dots, 1]$ ,  $a \in [2^{-10}, 2^{-1}]$ . Above each figure we illustrate the process of subdivision leading to each Cantor set.

FIG. 2 Wavelet analysis of fully developed turbulence from wind-tunnel data. Coordinates and intensities are as in Fig. 1. The top graphs show the signals being analysed. Panel *a* is a 852-m-long sample, showing the large scales (from  $28l_0$  to  $l_0/10$ ) analysed using a 'French top hat' wavelet. In *b* the

'Mexican hat' wavelet was used for magnification  $\times 20$  of the central position indicated by the arrow in the top graph of *a*. Panel *c* bears an analogous relation to *b*, again using the 'Mexican hat' wavelet. The successive forkings reveal the fractal nature of the Richardson cascade.

fraction  $\beta$  of the eddies of smaller scales. More recently, a multifractal model of the fine-scale intermittency has been introduced by Parisi and Frisch<sup>5</sup>; this accounts for the more complex cascading process suggested by the experimental data on inertial-range structure functions obtained by Anselmet *et al.*<sup>6</sup>. These statistical models are insufficient, however, because they cannot give any topological information about the intermittent structures in real space. Here we use the wavelet transform<sup>7</sup> to analyse the velocity field of wind-tunnel turbulence at very high Reynolds numbers<sup>8</sup>. This 'space-scale' analysis is shown to provide the first visual evidence of the celebrated Richardson cascade<sup>1</sup>, and reveals in particular its fractal character<sup>3</sup>. The results also indicate that the energy-cascading process has remarkable similarities with the deterministic construction rules of non-homogeneous Cantor sets<sup>9,10</sup>.

Wavelet analysis<sup>7</sup> is a mathematical technique introduced recently for analysing seismic data and acoustic signals<sup>11,12</sup>. It provides a two-dimensional unfolding of one-dimensional signals, resolving both the position and the scale as independent variables. The method comprises an expansion of an arbitrary real-valued function  $s(x)$  over wavelets that are constructed from a single function  $g$  by means of dilatations and translations<sup>7,13</sup>. The wavelet transform of  $s(x)$  with respect to the wavelet  $g$  is defined as:

$$T_g(a, x) = w(a) \int g((x-y)/a) s(y) dy \quad a > 0, x \in \mathbb{R}$$

where the weight function  $w(a)$  is introduced for visual enhancement.

The wavelet  $g$  is a regular function, localized around  $x=0$ . For a large class of functions  $s(x)$ , the wavelet transform may be inverted, provided that  $g$  is admissible ( $\int g(y) dy = 0$ ) and satisfies others conditions<sup>7,14</sup>. The wavelet transformation can be regarded as a mathematical microscope<sup>9</sup>, for which position and magnification correspond to  $x$  and  $a^{-1}$ , respectively, and the performance of the optics is determined by the choice of the analysing wavelet  $g$ . Wavelet analysis has become a powerful tool for locating singularities<sup>9,10</sup>: a singularity of  $s(x)$  at  $x_0$  produces a cone-like structure in  $T_g$ , pointing towards the point ( $a=0, x=x_0$ ). The nature of the singularities may be inferred from the power-law behaviour of  $T_g(a, x=x_0)$  on increasing the magnification  $a^{-1}$ .

As emphasized by Arnéodo *et al.*<sup>9</sup>, the wavelet transform assists visualization of self-similar properties of fractal objects. In particular, it illustrates the complexity of the fractal under consideration, revealing the hierarchy that governs the relative positioning of the singularities. In Fig. 1a, the successive pitchfork branchings observed in  $T_g(a, x)$  as a result of increasing the magnification  $a^{-1}$  illustrate how the uniform (single-scale) triadic Cantor set is constructed<sup>9,10</sup>. The unit interval  $[0, 1]$  is initially divided into three sub-intervals, each of length  $l=1/3$ . The middle interval is removed and the same process is repeated on each of the two remaining sub-intervals, and so on *ad infinitum*. In Fig. 1b, the same analysis is performed for the multifractal (two-scale) Cantor set that arises at the onset of chaos through the period-doubling cascade scenario<sup>9,15</sup>. The pitchfork branchings observed on increasing the magnification  $a^{-1}$  are no longer symmetric, and occur not in pairs but successively, as the signature of two unequal scaling factors, one large and one small ( $L(\alpha_{PD}) \approx 1/2.5029 \dots$ ) and  $S(\alpha_{PD})$  respectively). Moreover, the internal self-similarity of  $T_g$  (which is central to the renormalization-group study of the period-doubling transition to chaos) illustrates the basic construction rule of the period-doubling Cantor set: from one stage to the next, the relative positions of the large and small sub-intervals is unchanged when dividing a small interval, but is exchanged when dividing a large interval.

The fractal structures proposed in fully developed turbulence are real-space structures, in contrast to fractal attractors, which reside in phase space. Thus the wavelet transform can be applied

directly to turbulent velocity fields obtained from experiment or from numerical simulations<sup>16</sup>. Here we report the first such analysis performed on the velocity data from high-Reynolds-number, three-dimensional turbulence. The data were obtained in the large wind tunnel S1 of ONERA in Modane, France. A hot wire probe was located on the axis of the return section which was 24 m in diameter and 150 m in length. The turbulence level, expressed by the ratio of the r.m.s. value of the longitudinal velocity fluctuations to the mean velocity, was less than 7%, which implies that time variations are equivalent to spatial variations (the Taylor hypothesis). The scale ratio of the velocity signal shown in Fig. 2 is about  $4 \times 10^4$ , giving 15 m for the integral scale  $l_0$  and 0.35 mm for the dissipation scale  $l_d$ . The Reynolds number based on the Taylor microscale is  $R_\lambda = 2,720$ . This turbulence has an inertial range of at least two decades<sup>8,17</sup>.

A signal of total length 852 m was analysed hierarchically. Figure 2a corresponds to the total span and to a range of scales (that is, of parameter  $a$ ) from  $28l_0$  to  $l_0/10$ . Figure 2b shows the region around the arrow in Fig. 2a, with position and scale variables magnified by a factor of 20, and Fig. 2c is related to Fig. 2b in the same way. A 'French top hat' piecewise constant analysing wavelet was used in the case of Fig. 2a, emphasizing the cone-like structures. A 'Mexican hat' wavelet was used in Figs 2b and c, because it provides a (marginally) better visualization of the Richardson cascade<sup>1</sup>. Only positive values of the wavelet transform are shown. In the figures the weight function  $w(a)$  was chosen such that the maximum of  $T_g(a, x)$  on each  $a = \text{const.}$  line is independent of  $a$ .

Large-scale eddies are revealed in Fig. 2a by the superimposed cone-like patterns of different intensities, indicating structures of scale  $a \sim l_0$ . These large-scale structures seem randomly distributed in space and are fairly space-filling. Very different small-scale patterns are displayed in Figs 2b and c. These are created by a process in which typically an eddy divides asymmetrically (in intensity) into two smaller eddies, and this subdivision is repeated about eight to ten times before eddies reach a scale at which they are readily dissipated. These successive forkings produce a fractal structure, in which small-scale activity becomes increasingly sparse. The ratio between the scales of successive generations can take different values, which is another indication that a multifractal description is appropriate.

In summary, we have used wavelet analysis, which is already known to be a powerful tool for analysing multifractal attractors<sup>9,15</sup>, to explore the spatial structure of fully developed turbulence. Our emphasis has been to identify new qualitative features. Similar techniques can be used to reveal fractal clustering of galaxies on very large scales (A. Bijaoui & E. Slezak, unpublished work). □

# The 1988 US drought linked to anomalous sea surface temperature

T. N. Palmer & Č. Branković

European Centre for Medium Range Weather Forecasts,  
Shinfield Park, Reading, RG2 9AX, UK

THE 1988 drought in the United States has been widely reported, not least as an indicator of the reality of the 'greenhouse effect'—see for example ref. 1. On the other hand, drought is a naturally occurring phenomenon. Here we have studied 30-day forecasts of the atmospheric flow over the United States using a complex numerical weather-prediction model initialized with data from May 1987 and May 1988. In addition, an experiment with 1988 initial conditions and 1987 sea surface temperatures was made. The results indicate that much of the difference between the 1987 and 1988 forecasts was associated with interannual variability in sea surface temperature. These results provide complementary evidence to that in ref. 2, which suggested that the US drought was linked to anomalous oceanic conditions in the tropical Pacific.

The El Niño event in the tropical Pacific ocean is now recognized as part of the natural variability of the coupled ocean-atmosphere system<sup>3</sup>. At its height, the El Niño event is associated with an anomalous warming of the surface waters of the east and central tropical Pacific. There have been many studies suggesting that in the northern winter, there is a link between this warming and unusual weather conditions in the extratropics<sup>4</sup>. During 1987 there was a moderate El Niño event. In 1988, however, conditions in the tropical east Pacific began to swing towards the opposite, 'anti El Niño' or 'La Niña', phase of the event where sea surface temperatures (SSTs) became anomalously negative. Little is known about the possible impact of La Niña in the extratropics.

The difference between SSTs averaged for the 15 days preceding 24 May 1987 and 22 May 1988 is shown in Fig. 1a. The relative warmth of the equatorial east Pacific in 1987 relative to 1988 (over 3 K), is clearly shown. To the north and south of this equatorial band, SST differences were reversed. It should be pointed out, however, that there were significant SST differences in other parts of the globe. As shown, differences of 3 K were also attained in the subtropical north Pacific, and differ-

ences of 2 K were observed in the Atlantic and Indian oceans. Whether these are causally linked to the El Niño cycle is unknown at present.

Figure 1b shows the observed time-average difference in the height of the atmospheric 300-mbar pressure surface between 25 May–23 June 1987 and 23 May–21 June 1988. Over much of North America the pressure surface was lower in 1987 than 1988. This is consistent with the fact that, during the 1988 drought, the jet stream and associated rain-producing weather systems were displaced northward of their usual positions by anomalous high pressure. Relative to 1988, the height of the 300-mbar surface was also depressed over a region extending from Alaska down to the subtropical north-east Pacific. Note also that there is a rather strong negative depression over the north-west Atlantic.

Based on observations of the anomalous height fields for 1988, and using theoretical concepts of Rossby-wave radiation from a tropical heat source, and a relatively simple numerical model, Trenberth *et al.*<sup>2</sup> suggested that the 1988 US drought and anomalous tropical Pacific SSTs were causally related, and inferred that the 1988 US drought was part of normal climatic variability.

The European Centre for Medium Range Weather Forecasts (ECMWF) has developed a complex and comprehensive global numerical weather-prediction model<sup>5</sup> which is integrated daily to give weather guidance up to ten days ahead. On an experimental basis over the past four years, the model has also been integrated to 30 days, twice a month, from initial data separated by 24 h. In general, the day-to-day variations of weather are not predictable beyond about two weeks into the future. However, from time to time, the 30-day extended range forecasts do show impressive skill (that is, the forecast and observations correlate well).

Figure 2 shows some 30-day mean difference fields from extended-range forecasts initialized on 24 May 1987 and 22 May 1988. Comparing the forecast 300-mbar height field difference in Fig. 2a with the observed height field difference (Fig. 1b), it can be seen that the difference in model simulations for the two years is quite skilful. In particular, the three depressions of the actual 300-mbar height surface described above, over the Atlantic, North America and the North-east Pacific, all have counterparts in the forecast field. Although the two fields clearly do not correlate perfectly, the verisimilitude of this extended-range forecast difference field is in general above average. Indeed the difference field for two 30-day forecasts, each initialized just

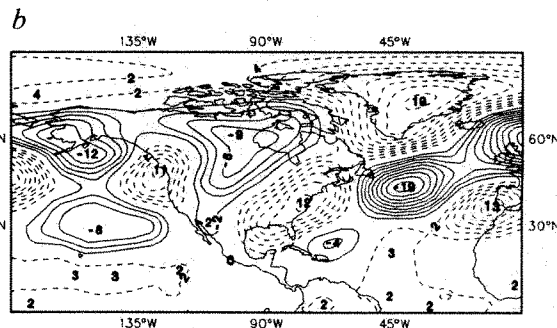

FIG. 1 a, Difference in sea surface temperatures between data averaged for 15 days preceding 24 May 1987, and for 15 days preceding 22 May 1988. Contour interval of 1 K. Areas above 0.5 K shown with coarse stipple; areas below -0.5 K shown with fine stipple. The two SST fields whose difference is shown here were used as oceanic boundary conditions for the model

integrations discussed in the text. Data from operational US National Meteorological Center analyses. b, Time-average difference in the height of the 300-mbar pressure surface between the 30 days following 24 May 1987 and the 30 days following 22 May 1988. Contour interval 20 cm. Positive values are shown with dashed contours.

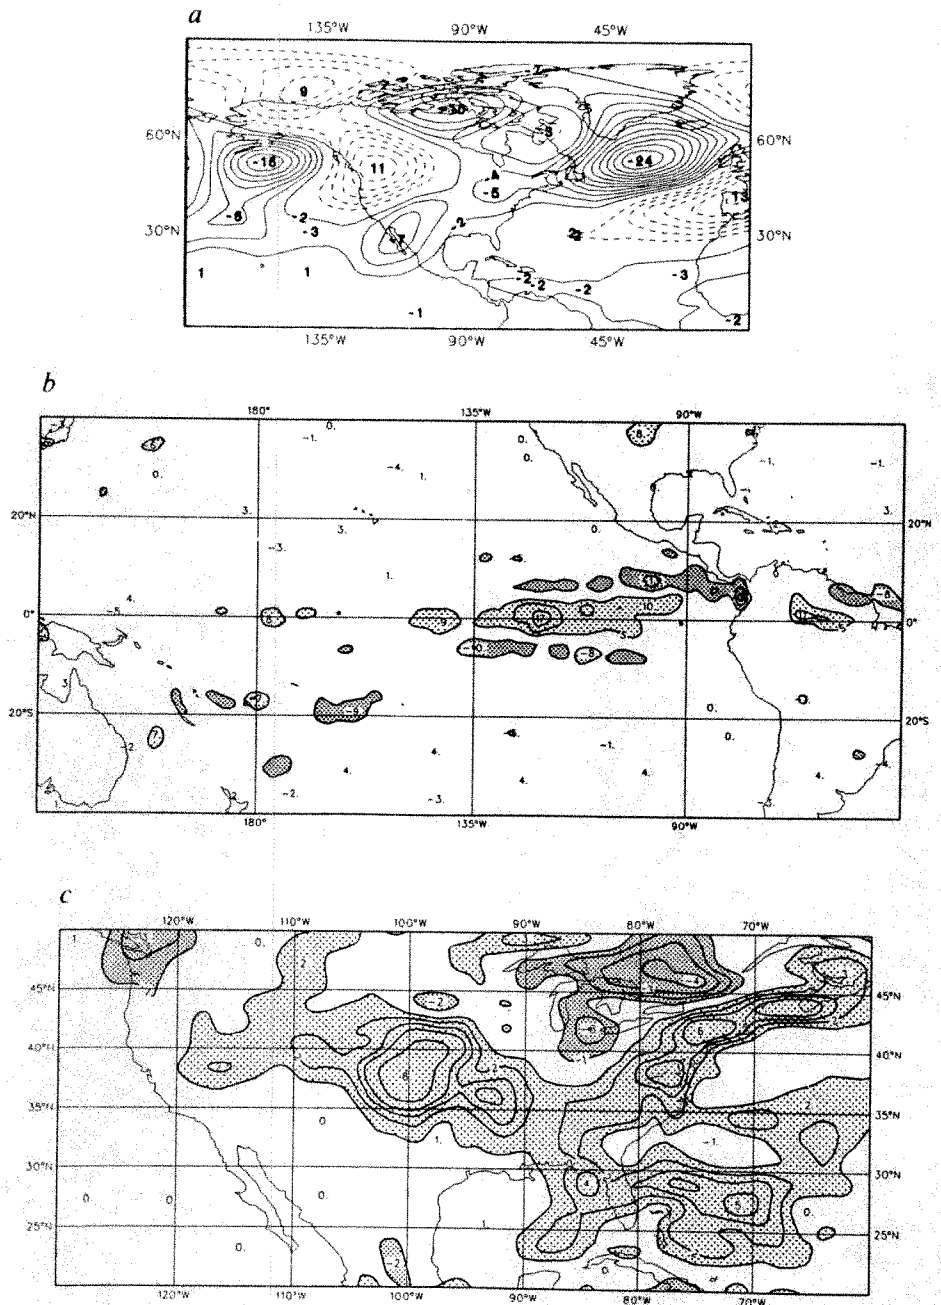

FIG. 2 Thirty-day average difference fields between two forecast integrations of the (T63) ECMWF numerical weather prediction model, the first initialized from data for 24 May 1987, the second from 22 May 1988. *a*, The height of the 300-mbar pressure surface, contours as Fig. 1*b*. *b*, Rainfall over the east tropical Pacific with contour interval of 5 mm per day (0 contour suppressed), coarse stippling above 5 mm per day, fine stippling below -5 mm per day. *c*, Rainfall over North America with contours of  $\pm 6$ ,  $\pm 4$ ,  $\pm 3$ ,  $\pm 2$ ,  $\pm 1$  mm per day; coarse stippling above 1 mm per day, fine stippling below -1 mm per day.

one day earlier than those shown here, was very much poorer. The sensitivity of extended-range forecasts to initial conditions can be expected on fundamental theoretical grounds<sup>6</sup>.

Figure 2*b* shows 30-day mean forecast difference rainfall fields over the tropical Pacific. Over the equatorial east Pacific there is a clear increase in rain in 1987 compared with 1988. To the immediate north and south, there is a relative decrease in 1987. This field is clearly correlated with the SST difference field shown in Fig. 1*a*, and agrees with satellite remote-sensing proxy observations of rainfall<sup>7</sup>.

Figure 2*c* shows 30-day mean forecast difference rainfall fields over North America. Over much of the eastern and central United States, the differences are generally positive and substantial, indicating in some areas a forecast of rainfall for 1988 less than 20% of that for 1987. Of course, these rainfall difference fields are not accurate in detail, but certainly capture much of the essence of the 1988 drought<sup>7</sup>.

The question arises as to whether the difference fields shown in Fig. 2 reflect primarily the fact that the initial conditions between the two integrations were different, or whether the

'boundary conditions' also played an important role. In numerical weather-prediction models (as opposed to many climate models), SSTs are specified and held fixed during an integration, and are therefore part of the boundary conditions for such models. For the ECMWF forecasts, SSTs are obtained as an average of observations for 15 days preceding the initial date. Figure 1*a* shows the difference field of SSTs used in the two forecasts.

To examine the importance of SST differences in accounting for the difference fields in Fig. 2, we have run a third 30-day integration using identical conditions to the 1988 forecast, but with SSTs from the 1987 integration. The difference in 30-day mean 300-mbar height and rainfall between this experiment and the 1988 forecast integration is shown in Fig. 3.

In testing the potential impact of SST anomalies on the atmosphere, it is common to run a single climate timescale integration of several years, or a large number of shorter timescale integrations from a variety of initial conditions. In the latter case, the impact of SSTs will in general depend quite strongly on the particular initial conditions<sup>8,9</sup>, and it may be

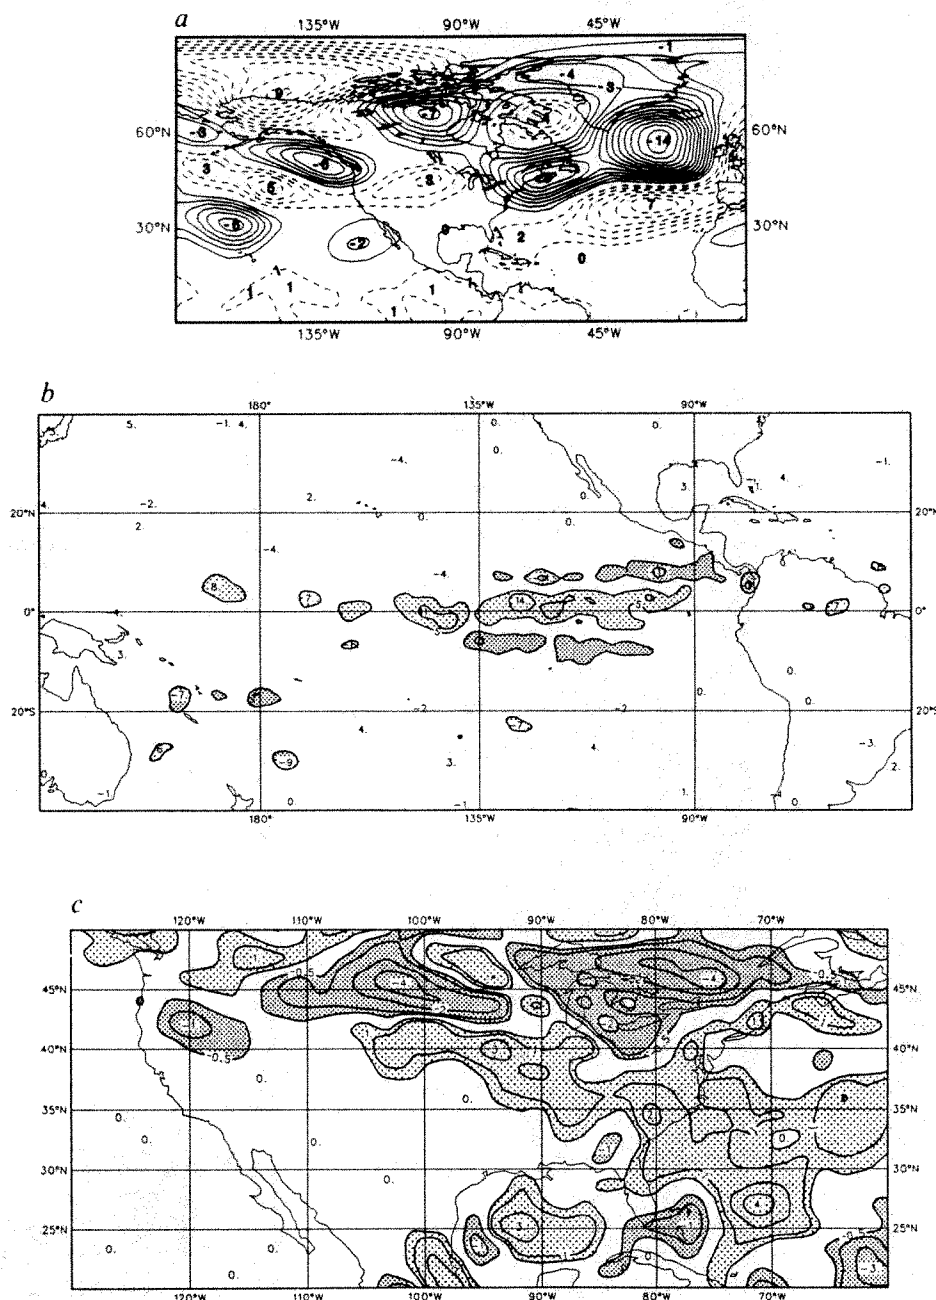

FIG. 3 Thirty-day average difference fields between two integrations of the (T63) ECMWF numerical weather prediction model; the first initialized from data for 22 May 1988 and sea surface temperatures from the 15 days preceding 24 May 1987, the second initialized from the same data but with sea surface temperatures averaged from the 15 days preceding 22 May 1988. *a*, The height of the 300-mbar pressure surface; contour interval 10 cm. *b*, Rainfall over the east tropical Pacific, contours as Fig. 2*b*. *c*, Rainfall over North America with contours of  $\pm 5$ ,  $\pm 3$ ,  $\pm 2$ ,  $\pm 1$ ,  $\pm 0.5$  mm per day; coarse stippling above 0.5 mm per day, fine stippling below  $-0.5$  mm per day.

that one would deduce that the response of the atmosphere to a particular SST anomaly was not strongly significant. If one has the option, however, of verifying the shorter-timescale integrations as forecasts, one finds that many, if not most, show little extended-range forecast skill, although a small (maybe very small) fraction show exceptional extended-range skill. The question then arises as to whether the response of the unskilful forecasts to the imposed SST anomalies should be given the same weight as the response to the skilful forecasts (as would conventionally be the case). We suggest that they should not. This is the reason why we choose to emphasize the response to our skilful forecast, rather than the unskilful forecast initialized one day earlier. (In fact one could broadly think of our results in terms of an ensemble mean of two forecast experiments, weighted *a posteriori* by the extended-range skill of the basic forecast.)

The 300-mbar height difference field (Fig. 3*a*) is clearly correlated with the forecast difference field shown in Fig. 2*a*, although the amplitude of the field is smaller (note the reduced contour interval in Fig. 3*a*). Note, in particular, the depression of the

height of the 300-mbar surface over the Atlantic and over North America. The depression over the North Pacific is certainly not as strong in Fig. 3*a* as in Fig. 2*a*, although the general pattern of wind anomalies that would result from these height field differences corresponds well.

Rainfall differences over the tropical Pacific are shown in Fig. 3*b*. Comparing with Fig. 2*b*, there can be no doubt that the simulated difference between 1987 and 1988 rainfall in that region is primarily the result of the different boundary conditions.

Rainfall differences over North America are shown in Fig. 3*c*. It can be seen that there is a general increase in rainfall with 1987 SSTs to the south of  $40^\circ$  N, and the pattern is well correlated with the forecast difference in Fig. 2*c*. Moreover, there is a decrease in rainfall over the Great Lakes area, consistent with the decrease there in Fig. 2*c*. Again, it should be emphasized that Fig. 3 should be compared with Fig. 2 rather than the observations; shortcomings in the veracity of the forecast fields are reflected in similar shortcomings for the experiment.

These results clearly indicate that the impact of the SSTs was

in the same sense as the difference between the two forecasts. The amplitudes in Fig. 3 are clearly smaller than in Fig. 2, because the impact of the SSTs is not felt to any significant extent in the first few days of the forecast.

Hence we conclude that the anomalous SSTs in 1987 and 1988 were indeed important in accounting for the reduction in rainfall over the United States in the late spring of 1988. We cannot, on the basis of these results, state that La Niña itself (rather than other regions of SST anomaly) was principally important. Further experiments should help to clarify this. However, on the basis of this study and the investigation of Trenberth *et al.*<sup>2</sup>, using very different techniques to those discussed here, tropical Pacific ocean temperatures related to the El Niño/La Niña event cycle appear to be important, and there now seems to be mounting evidence that the 'cause' of the 1988 US drought was primarily associated with phenomena that are part of the natural variability of the climate system. □

## Organic geochemical evidence for global fires at the Cretaceous/Tertiary boundary

M. I. Venkatesan & J. Dahl

Institute of Geophysics and Planetary Physics,  
University of California, Los Angeles, California 90024-1567, USA

MANY hypotheses have been advanced to explain the mass extinction at the Cretaceous/Tertiary (K/T) boundary<sup>1–3</sup>. Recently, Wolbach *et al.*<sup>4</sup> suggested that massive forest fires were triggered by the impact of a meteorite, and cite as evidence the presence of elemental carbon (mainly soot) from K/T boundaries<sup>5</sup>. Almost all of the airborne polycyclic aromatic hydrocarbons (PAHs) generated by pyrosynthesis are adsorbed, through hydrogen bonding, on the surface of soot, the particulate fraction from combustion<sup>6,7</sup>. Although soot itself is a polymer of polybenzenoid radicals, early termination of polymerization leads to enhanced PAH production. Pyrosynthesis of PAHs is thus favoured by a chemically reducing atmosphere. If there were wildfires, a group of high-molecular-weight parent PAHs characteristic of combustion, predominating over their alkyl homologues<sup>8,11</sup>, should be present in K/T boundary samples known to contain soot<sup>4,5</sup>. Here we compare K/T samples from New Zealand, Italy and Denmark to those from above and below the boundary, and find enhanced PAH contents and distribution profiles that reflect a pyrolytic origin. The data thus provide the first detailed organic-molecular evidence for the combustion source of organic carbon at the K/T sites.

The organic-rich clay layer (corresponding to S6 to S10 of Schmitz<sup>12</sup>) above the red layer was collected by B. Schmitz by digging into the Fish Clay outcrop at Stevns Klint, Denmark (200 m south of the Højstrup Church). Only the unweathered clay was gathered. Woodside Creek boundary clay (upper layer) and two samples, one well into the Tertiary and the other well into the Cretaceous, were obtained from R. R. Brooks (Table 1). The exact location, stratigraphy and other details of depositional environment are available<sup>13,14</sup>. The red boundary clay, and a sample from above and below the boundary, from Bottaccione Gorge, Gubbio, Italy, were collected by W. Cavazza.

Sample location and trace-element distribution are described in ref. 15. The samples were shipped by air in sealed plastic bags, some first wrapped in aluminium foil.

Chunk samples were quickly sonicated in dichloromethane to remove external contamination. Dry powdered samples were then extracted in dichloromethane and fractionated into aliphatic and aromatic hydrocarbons and other classes of compound according to the methods of Venkatesan *et al.*<sup>16</sup>, which involve thin-layer and column chromatography. The aromatic hydrocarbon fraction (containing PAHs) was analysed by gas chromatography and quantified by gas chromatography/mass spectrometry (GC/MS), based on the response factor of an internal standard (dodecylbenzene) and an external standard mixture containing PAH compounds listed under Fig. 1.

Pertinent geochemical data are presented in Table 1. The iridium enrichment at the boundary clays is generally concomitant with the enhanced levels of organic carbon and total PAH content. This is also consistent with a recent observation<sup>17</sup> that the bulk of the iridium is probably organically complexed.

The distribution of PAHs in K/T extracts is illustrated in Fig. 1. The Stevns Klint and Gubbio samples are enriched in high-molecular-weight PAHs relative to the Woodside Creek sample. Phenanthrene is the most dominant and 2-methylfluorene the second most dominant PAH in the Woodside Creek sample. In the Stevns Klint sample, coronene is the most abundant PAH, followed by phenanthrene. Coronene is also the most dominant PAH in the Gubbio sample, followed by benzo(*b+k*)fluoranthene and chrysene/triphenylene. Pyrene and fluoranthene are significant constituents in the Stevns Klint and Gubbio samples. The dominant analogues in both of these samples are the peri-condensed aromatic series, such as pyrene, benzo-pyrene, benzo(*g,h,i*)perylene and coronene. These peri-condensed compounds are formed by the pyrolysis of organic matter<sup>18</sup> such as gasoline<sup>19</sup> and wood<sup>20</sup>, and are relatively uncommon in petroleum<sup>6</sup> but have been detected in significant amounts in hydrothermal mounds<sup>21</sup>. Because peri-condensed structures are more reactive than their angularly-condensed analogues<sup>18</sup>, the presence of the former in significant amounts in these samples implies that rapid thermal quenching by adsorption of these PAHs in soot contributed to their stability. Also, the abundance of these pyrolytic PAHs should have been high compared with that seen today, the latter representing the residual combustion PAHs after degradation<sup>19</sup>.

The absence of peri-condensed PAHs in the Woodside Creek K/T sample could be attributed to one of the following. (1) They were not formed because there were no wildfires. (2) The continent adjacent to this site experienced elevated temperatures for longer intervals relative to the other two sites, with

§ Data from ref. 15.

consequent elimination of the less stable, intermediate<sup>18</sup>, peri-condensed PAHs. No literature data is available at present on the stability of peri-condensed PAHs and their burial history. The presence of five-membered alicyclic rings such as 2-methylfluorene, 2,3-benzofluorene and fluoranthene also attest to the pyrolytic origin of PAHs in all three of the sites. These PAHs are commonly present in all pyrolysates from organic matter and, once formed, are not easily converted to peri-condensed aromatics, because they inhibit subsequent enlargement of the aromatic nuclei<sup>18,22</sup>. Thus the chemical composition of the PAH fraction suggests a pyrolytic source. The Woodside Creek K/T sample, therefore, reflects input of PAHs from combustive sources, possibly from an adjacent land mass that experienced extended periods of high temperatures caused by forest fires, resulting in the destruction of less stable, linear PAHs<sup>18</sup>. (3) The Woodside Creek site shows considerable lateral variations in boundary-clay thickness and Ir abundances, which are apparently also reflected in the PAH profile. This may explain the relatively high level (1.4 parts per 10<sup>9</sup>) of coronene reported earlier from a Woodside Creek K/T layer<sup>23</sup>.

The dominance of parent PAHs is characteristic of combustion products, whereas alkylated PAHs predominate in bitumen and petroleum<sup>8-11,22</sup>. The predominance of parent PAHs in the boundary samples (Fig. 2) indicates that they have been subjected to far higher temperatures than those involved in petroleum formation. On the other hand, the two samples above and below Woodside Creek K/T boundary are enriched in alkyl

homologues and exhibit patterns characteristic of petroleum<sup>8-11,22</sup>. However, the effects of biodegradation and water washing<sup>24</sup> and weathering<sup>25</sup> necessitate caution in interpreting the PAH data. Data from other lipid components indicate that both the Stevns Klint and Woodside Creek samples are biodegraded, although not to the extent of total removal of *n*-alkanes (J. D. *et al.*, preprint). Weathering could cause the removal of alkylated PAHs<sup>25</sup>, resulting in a pyrolytic profile. However, comparison of the unresolved complex mixture of aliphatic-fraction and normal-alkane profiles from Woodside Creek indicates that the three samples (K/T, +250 cm, -275 cm) apparently were subjected to similar extents of weathering (J. D. *et al.*, preprint; M. I. V., unpublished data). Yet samples above and below the boundary exhibit PAH alkyl homology significantly different from that at the boundary, suggesting that the boundary experienced an input of combustion PAHs significantly above the background level. It is also known that parent PAHs are more susceptible to biodegradation than are the alkyl PAHs and that the rate of biodegradation decreases with increasing degree of alkylation under oxic conditions<sup>24</sup>. Assuming that some biodegradation has occurred, the elevated abundance of parent PAHs relative to alkyl PAHs at the boundary provides convincing evidence for an input of combustion material to the boundary layer.

Alkyl homology at the boundary is similar to that in the profiles reported from soot<sup>11</sup> and recent sediments receiving airborne combustion inputs<sup>8-11</sup> (Figs 2 and 3). The alkylation

FIG. 1 PAH distribution at the K/T boundaries. The following compounds in the external standard mixture were quantified: naphthalene (NAP); 2-methylnaphthalene (2MN); 1-methylnaphthalene (1MN); biphenyl (BPH); 2,6-dimethylnaphthalene (DMN); acenaphthene (ACN); 2,3,5-trimethylnaphthalene (TMN); fluorene (FLU); 2-methylfluorene (2MF); dibenzothiophene (DBT); phenanthrene (PHN); anthracene (ANT); fluoranthene (FLA); pyrene (PYR); 2,3-benzofluorene (BFLU); 1,1'-binaphthalene (BNAP); benzo(a)anthracene (BAA); chrysene/triphenylene (CHR); benzo(b+k)fluoranthene (BFLA); benzo(e)pyrene (BEP); benzo(a)pyrene (BAP); perylene (PER); 9,10-diphenylanthracene (DPA); 1,2,5,6-dibenzanthracene (DBA); benzo(g,h,i)perylene (BPER); anthanthrene (ANTA); coronene (COR); 1,2,4,5-dibenzopyrene (DPYR). Numbers printed above some compounds refer to concentrations too low to be plotted. Quantification was carried out with a Finnigan Model 4000 quadrupole mass spectrometer interfaced directly with a Finnigan Model 9610 gas chromatograph. A fused-silica DB5 (J&W) column of 30 m  $\times$  0.25 mm was programmed from 35  $^{\circ}$ C to 290  $^{\circ}$ C at 4  $^{\circ}$ C min<sup>-1</sup> and then held at constant temperature for  $\sim$ 2 hours. Helium was used as a carrier gas; electron energy was 70 eV; source temperature was 240  $^{\circ}$ C; scan speed 2 s per scan from 50 to 550 AMU. Analyses were performed in the full scan mode and the extracted-ion-current profiles were used in the identification and quantification. The PAH fraction was also screened for substitution by alkyl homologues up to C<sub>4</sub> to C<sub>5</sub> (from NAP to PER), in addition to those listed above.

patterns of K/T samples from Woodside Creek and Gubbio are characteristic of combustion products of wood or kerosene, whereas the Stevns Klint profile is more akin to that from combustion of coal<sup>22</sup>. These patterns can originate from combustion at temperatures of 400–800 °C (as occur during forest fires), which could allow some alkylated PAHs to survive while thermally cracking extended chains into radicals, which recombine to form larger aromatic systems by pyrosynthesis<sup>8</sup>.

Based on the detection of retene (1-methyl-7-isopropyl-

phenanthrene) in Woodside Creek<sup>5</sup> and in the DSDP site 605 (ref. 26), biomass is considered a strong candidate as the fuel for such a fire<sup>5</sup>. We detected retene and simonellite at  $<1$  part per  $10^9$  in the K/T samples, indicating that although biomass may have been a fuel source, the retene concentration is too low to confirm this. Alkylated phenanthrenes have indeed been detected in volcanic ash from Mt St Helens as a result of pyrolysis of plant material<sup>27</sup>, and in emissions from wood combustion<sup>20</sup>. The yield of retene apparently depends on oxygen availability

FIG. 2 Alkyl homologue distributions of selected PAHs. The most abundant homologue in each sample is set to 1.0.

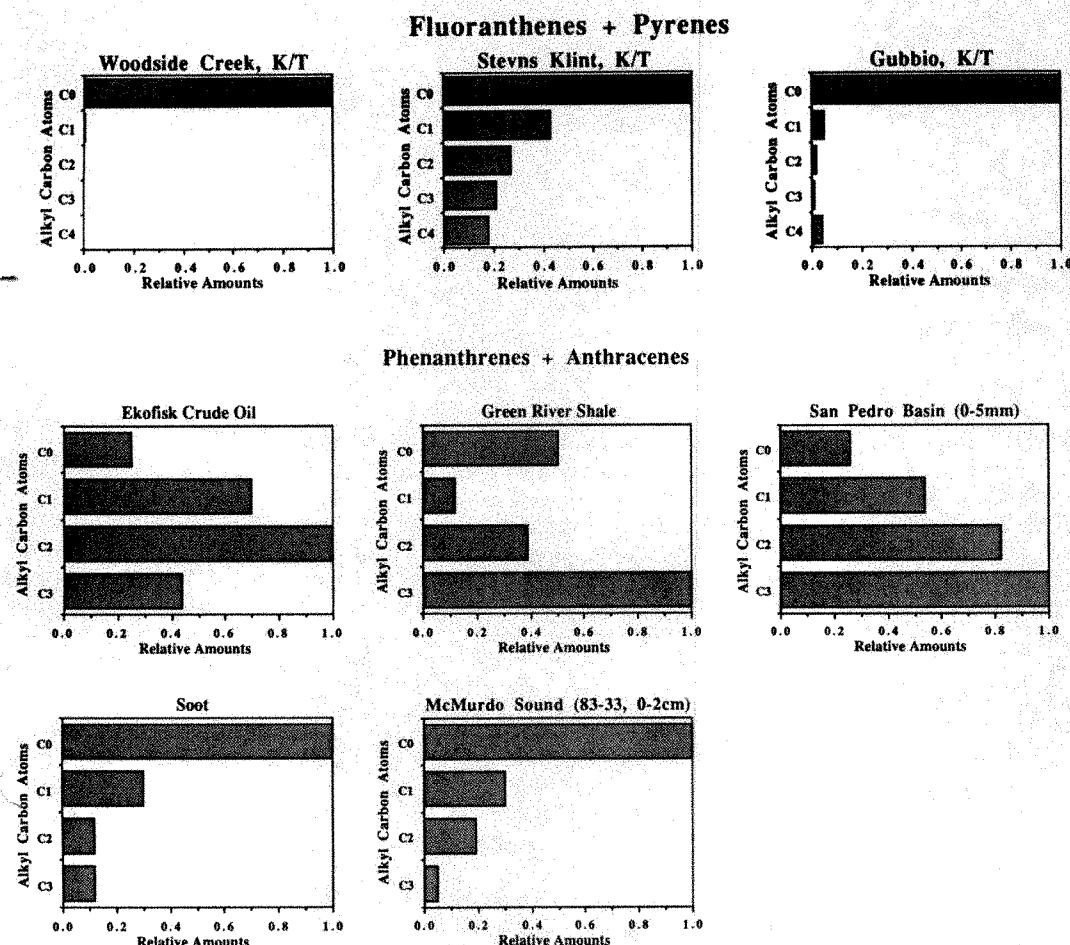

FIG. 3 Alkyl homologue distributions of phenanthrenes + anthracenes plotted from selected literature data. Note the enrichment of alkylated PAHs in oil<sup>24</sup>, shale and recent, petroleum-contaminated sediment from San Pedro Basin, southern California Bight<sup>10</sup>. Recent sediment from McMurdo Sound<sup>28</sup>, Antarctica, illustrates the combustion PAH profile, similar to that found in soot. Airborne combustion characteristics of PAHs in the Antarctic sediments are described in ref. 29. Soot data are plotted from ref. 11. Note the similarity of K/T boundary samples to McMurdo Sound PAH profile, and those of the Woodside Creek K/T +250 and -275-cm to the San Pedro Basin PAH profile.

and is inversely proportional to temperature<sup>20</sup>. The relatively low ratio of retene to other PAHs (such as phenanthrene) in the K/T boundary clays is consistent with moderate- to high-temperature (400–800 °C) pyrosynthesis<sup>6</sup>. However, the low amounts of retene could also reflect a contribution from diagenesis of dehydroabietic acid<sup>28</sup>, which would bring into question a thermal origin of retene from biomass fires.

In conclusion, our data suggest that the PAH distributions at the K/T boundary from Woodside Creek, Stevens Klint and Gubbio are characteristic of a combustion origin, which is consistent with the earlier suggestions of massive global fires<sup>4,5</sup>.

**DIAMONDS** are found in several areas of the world where their currently accepted source, kimberlite/lamproite volcanism, has not been found. Garnet pyroxenite layers in the Beni Bousera peridotite massif, northern Morocco, contain octahedral and other cubic forms of graphite, which we interpret here as pseudomorphs after diamond. This occurrence demonstrates that fragments of highly diamondiferous mantle are tectonically emplaced into the continental crust, providing an alternative source for some diamonds.

The Beni Bousera peridotite massif forms part of the Betico-Rifean Fold Belt. A continuous gravity high between Beni

FIG. 1 Photograph of upper half of a sharp-edged octahedron protruding from the garnet pyroxenite layer.

Bousera and the Ronda peridotite in south-west Spain<sup>1</sup> indicates that the Betics and Rif are part of the same tectonic system. Both the Beni Bousera and Ronda massifs were emplaced into the crust at high temperature during the Alpine orogeny<sup>2,3</sup>. In addition to peridotites, both massifs contain many mafic layers of varying composition. The predominant rock type within the Beni Bousera peridotite massif is a variably altered spinel lherzolite accompanied by rare harzburgites and dunite pods. Mafic layers form up to 10% of the outcrop<sup>4</sup>. Four garnet clinopyroxenite layers are known to contain graphite octahedra<sup>5</sup> (Fig. 1). The graphite pyroxenite layers comprise orange pyrope almandine garnet and omphacitic pyroxene porphyroclasts with minor amounts of plagioclase, spinel and sulphides. Graphite forms up to 15% by volume of the layers, and never cross-cuts the layer margins into the surrounding peridotites, which significantly contain no disseminated graphite. Graphite is also found in late-stage, low-temperature Cu–Ni mineralized veins which cross-cut the emplacement fabric of the massif. The graphite–garnet clinopyroxenites are not associated with this mineralization.

Graphite forms liberated by acid dissolution are multicrystalline assemblages of small graphite crystallites, here termed aggregates. They consist of (1) sharp-edged octahedra, with or without rounded fibrous graphite coats (the most abundant form); (2) rhombicuboctahedra<sup>6</sup> exhibiting well formed cube and octahedral faces; (3) contact twins or macles, with and without re-entrant angles, most of which are coated; (4) irregular to rounded masses whose surface morphology resembles framesite (phanerocrystalline carbonado<sup>7</sup>); and (5) octahedra that have been flattened and/or sheared along the {111} faces.

Graphite with no regular symmetry or form is widespread and probably represents highly deformed cubic forms. The regular crystalline forms of this graphite belong to the cubic system whereas natural graphite crystallizes in the hexagonal system. Graphite could be pseudomorphic after several cubic minerals. The most plausible geologically are diamond and spinel group minerals such as chromite and magnetite. Sub-millimetre anhedral spinel grains do occur in some mafic layers in Beni Bousera (less than 1% by volume). However, the relatively low Cr content (450–1,000 p.p.m.) of the bulk rock, and the low Cr and Fe<sup>3+</sup> content of the silicate minerals, are not consistent with the rock having once contained up to 15% of either chromite or magnetite. Additionally, petrographic studies show no evidence of either mineral as relicts within the graphite aggregates, and ashed graphites<sup>5</sup> confirm their absence.

All the regular crystalline forms of the graphite are displayed by natural diamond. Scanning electron microscopy (SEM) reveals that {111} faces of the graphite octahedral cores display pronounced steps which are comparable to the {111} growth

FIG. 2 *a*, Laue photograph of experimentally graphitized diamond, showing the strongly preferred orientation of graphite [0001] parallel to diamond {111} (courtesy of G. Cooper). Cu  $K\alpha$  radiation. plates observed on natural diamond. Also evident on the {111} faces are small pits of trigonal symmetry, which have similar geometry and orientation to the etched trigons on the faces of diamond from volcanic pipes. In addition, SEM observations demonstrate that the basal {0001} planes of graphite crystals in the core are approximately parallel to the {111} faces of the octahedra. In contrast, graphite crystals in the fibrous coat are much more irregular in their orientation, with their basal planes at a high angle, often perpendicular, to the {111} surfaces of the core. X-ray diffraction<sup>8,9</sup> (G. Cooper, personal communica-

FIG. 3 Scanning electron photomicrograph of a clinopyroxene inclusion within a graphite octahedron, displaying apparent cubo-octahedral faceting. The {100} and {111} facets of the inclusion are parallel to the {100} and {111} faces of the octahedron.

tion) reveals that the graphite produced by experimental graphitization of natural diamond between 4.8 and 10 GPa pressure produces graphite crystallites whose {0001} planes lie parallel to the {111} faces of the original diamond octahedra (Fig. 2*a*). Single-crystal X-ray diffraction patterns of the octahedral graphite forms from Beni Bousera sometimes show a strong preferred orientation similar to that observed on experimentally graphitized diamond (Fig. 2*b*).

Graphite exhibiting cubic morphology has been found previously only in extraterrestrial samples, in the form of cliftonite<sup>12</sup>. In these cases the multicrystalline graphite aggregates take the form of cubes, cubo-octahedra and pseudo-hexagonal outlines. These aggregates do not display the preferred orientation noted above. The sixfold axis of the graphite lies parallel to the [001] and [113] axes of the cliftonite<sup>13,14</sup> and thus these examples are not considered to be pseudomorphs after diamond<sup>13,14</sup>. Therefore, graphite pseudomorphing a cubic mineral will not necessarily acquire the preferred orientation seen in the Beni Bousera graphite.

Clinopyroxene and garnet are both observed as inclusions within octahedra in thin section. Radiographs indicate that these inclusions in the graphite octahedra occasionally occupy a large proportion of the interior. Some inclusions possess well formed cubo-octahedral facets identical to many inclusions within natural diamond<sup>10,11</sup> (Fig. 3). The mechanism by which diamond imposes cubic symmetry on minerals of lower symmetry, such as monoclinic pyroxene, is not clearly understood. However, this phenomenon is powerful evidence for a diamond precursor for the Beni Bousera graphite aggregates.

The Beni Bousera octahedral graphite aggregates display a sharp physical boundary between cores of cubic symmetry with regular crystallites, and rounded fibrous coats. In general, there is a difference in style of deformation between core and coat. Core graphite exhibits relatively coarse sub-grains when cut parallel to a cube axis, whereas the fibrous-coat graphite possess kink lamellae. These differences are due to the marked mechanical anisotropy of graphite, deformation style depending on the orientation of graphite basal planes with respect to the direction of principal stress. Raman spectroscopy (J. D. Pasteris, unpublished data) indicates that both coat and core graphite are extremely well crystalline and hence of high-temperature origin. The graphite aggregates are thus similar to coated diamonds; the latter are characterized by well formed cores, often clear octahedra, surrounded by diamond displaying a fibrous, radial growth, giving rise to the generally rounded

FIG. 4 Ternary Ca-Mg-Fe atomic-proportion plot of coexisting garnet-clinopyroxene-orthopyroxene in graphite garnet clinopyroxenites. The data are illustrated as fields, for clarity. Circles denote clinopyroxene, triangles denote orthopyroxene. Tie lines join coexisting phases of clinopyroxene and orthopyroxene. Fields for Orapa carbonaceous eclogites and inclusions in diamonds are shown<sup>20</sup>.

external morphology of thickly coated diamonds<sup>15,16</sup>. We conclude, therefore, that the graphite present in the garnet pyroxenites is the product of graphitization of diamonds, many of which may have been coated stones of some type.

The coats of coated diamonds are thought to be the result of rapid precipitation of diamond around a pre-existing nucleus associated with kimberlite genesis and eruption<sup>18</sup>. Our evidence may indicate that not all coated diamonds originate in this way.

The largest graphite aggregate consists of an octahedral core of edge length 12 mm surrounded by a coat 2–3 mm thick, such that the whole aggregate would be approximately equivalent to 10 carats if it were diamond. If all the graphite within the graphite-bearing garnet pyroxenite layers is assumed to be pseudomorphic after either macro- or micro-crystalline diamond, then the original diamond concentration of these layers would have been 15% by volume, that is, more than 10<sup>5</sup> times richer than the concentration found in high-grade kimberlites and lamproites but similar to concentrations in some small diamondiferous eclogite xenoliths<sup>18,19</sup>.

Major-element chemistry of graphitic and non-graphitic garnet clinopyroxenites is similar other than in respect of carbon contents. Compositions are also comparable to those of eclogite xenoliths found in kimberlite, being of picritic basalt composition (10.75–16.33% MgO) but having slightly lower total content of alkaline metals. The garnetiferous rocks from Beni Bousera, however, have undergone more extensive re-equilibration than have typical eclogite xenoliths, such that a significant proportion of the garnet has exsolved from clinopyroxene. Clinopyroxenes are aluminous sodic-augite to omphacite (up to 11.8 wt % Al<sub>2</sub>O<sub>3</sub>, 23 mol % jadeite) and fall within the field defined by carbonaceous eclogites<sup>20</sup> (Fig. 4). Garnets (Py<sub>57–34</sub>, Al<sub>48–29</sub>, Gr<sub>12–8</sub>) are within the large range measured from diamond-bearing eclogite xenoliths<sup>20</sup>.

Because of the essentially biminerallitic nature of the garnet pyroxenite layers, it is not possible to establish the pressures at which they last equilibrated. But microprobe studies using wavelength-dispersive methods demonstrate that despite substantial re-equilibration some garnets retain a slight excess of silica and small amounts of sodium (0.05 wt %). These compositions are comparable to those found in diamond-bearing eclogites and are a consequence of high-pressure pyroxene solid solution in garnet<sup>21</sup>, which becomes significant only at ~50 kbar pressure (depths of ~150 km), that is, within the stability field of diamond.

All of these lithologies contain evidence of lower-pressure re-equilibration. Garnet, orthopyroxene and plagioclase exsolution occur within clinopyroxene. There is no major- or trace-element compositional difference between garnet and clinopyroxenes included in graphite octahedra and those form-

ing the surrounding host rock (trace elements analysed by N. Shimizu, personal communication). This evidence implies that the inclusion and host-rock minerals have experienced the same pressure and temperature history, suggesting that silicate and diamond crystallization was co-genetic. This conclusion is further supported by the faceted nature of some inclusions.

Obducted ophiolites in Tibet<sup>22</sup> and Alpine peridotites in the Koryuk Mountains of the eastern Soviet Union and Armenia<sup>23</sup> are reported to contain very low concentrations of diamond. Alluvial diamonds, as yet of unexplained provenance but situated in the region of ophiolites or similar ultramafic belts including the Urals<sup>23</sup>, the Appalachians, Kalimantan (Borneo) and Copeton-Bingara (New South Wales), have no known volcanic sources<sup>24</sup>. The source rocks of these 'anomalous diamond occurrences', whether proven or suspected, are not eclogites but are mainly highly magnesian chromite harzburgites. These are similar to diamondiferous peridotite xenoliths in kimberlites except that garnet is usually lacking. Thus, rocks comparable to diamondiferous eclogite and peridotite xenoliths in kimberlite occur in some of the Earth's major collision zones, having been tectonically emplaced from close to the base of the lithosphere. Collision zones containing ultramafic massifs thus provide a potential economic source of diamonds.

# Coagulation on bubbles allows microbial respiration of oceanic dissolved organic carbon

Paul E. Kepkay & Bruce D. Johnson\*

Biological Oceanography Division, Department of Fisheries and Oceans, Bedford Institute of Oceanography, Dartmouth, Nova Scotia B2Y 4A2, Canada

\* Department of Oceanography, Dalhousie University, Halifax, Nova Scotia, B3H 4J1, Canada

DISSOLVED organic carbon in sea water (DOC) is one of the chief reservoirs of reactive organic carbon on the planet<sup>1</sup>. To determine the rate at which this carbon breaks down, a long-standing paradox must be solved. DOC appears to be remarkably unreactive<sup>2</sup>, yet it must be reactive to maintain the mass balance between organic carbon in the ocean and CO<sub>2</sub> in the atmosphere<sup>1</sup>. Here we show that the coagulation of colloidal DOC on bubble surfaces initiates the rapid microbial respiration of carbon which would otherwise be less accessible to the biota. This coupling of respiration to surface coagulation as a physical means of regenerating a substantial fraction (5–15%) of oceanic DOC could be a key factor in the mechanism required to recycle a recalcitrant reservoir of carbon back to CO<sub>2</sub>.

During August and September 1988, sea water was collected from a depth of 10 m on a transect of four stations across a highly productive tidal front on Georges Bank, and from four depths (from 10–85 m) at a station occupied for 9 days in the Sargasso Sea. On board ship all the sea water samples were filtered through 2- $\mu$ m Nuclepore membranes to remove the majority of particles without removing colloidal organic material<sup>3,4,5</sup> and were bubbled for 30 min in a glass column, using a 10–25  $\mu$ m glass frit to produce bubbles with an average diameter of 487  $\mu$ m (ref. 5). The air supplied to the frit was prefiltered through activated carbon and a sterile 0.2- $\mu$ m filter cartridge (Gelman) to ensure that contaminants were not introduced on bubble surfaces. After 30 min of bubbling, the sea water was divided into duplicate two-litre batches which were gently stirred in an incubator set at the appropriate *in situ* temperature. Two additional two-litre batches of filtered sea water were stirred at the same *in situ* temperature to act as unbubbled controls. Samples from all batches were taken at intervals to determine the rate of oxygen consumption by an oxygen gradient technique<sup>6</sup>.

The concept that aggregates of organic material and bacteria are generated by the coagulation of DOC on bubble surfaces has been discussed for over 25 years<sup>5,7</sup>. In our experiments this process of surface coagulation caused a rapid increase in microbial respiration, as measured by oxygen consumption rate (Figs 1 and 2). Respiration reached a maximum after 2–4 h and then declined to values similar to those found in unbubbled controls by 8–20 h. This is the first demonstration that surface coagulation can have a large, reproducible and systematic effect on microbial respiration in the open ocean—not only from the highly productive Georges Bank<sup>8</sup>, but also from a far less productive Sargasso Sea<sup>9</sup>. Without rapid sampling at the beginning of the experiments, we would have missed the dynamics associated with a transient microbial community and inferred that bubbling had no effect.

Many bubbling experiments have failed to show that surface coagulation has a significant effect on microbial communities<sup>5</sup>. Our experiments succeeded because we paid close attention to results obtained by Batoosingh *et al.*<sup>3</sup>, Johnson and Wangersky<sup>4</sup>, and Johnson *et al.*<sup>5</sup>. Filtering sea water through anything finer than a 2- $\mu$ m pore size removes larger colloids in the 0.2–1.2  $\mu$ m size range—a primary source of labile organic material for

FIG. 1 Respiration in bubbled sea waters (open circles) and unbubbled controls (closed circles) from a depth of 10 m at four stations on the NE quadrant of Georges Bank (47° 00'N; 67° 51'W). The transect of 4 stations included surface-water environments ranging from the mixed layer of a stratified water column in the Fundian Channel (station 21) to a tidal front at the edge of the bank (stations 2 and 3) and finally to well-mixed, particle-rich water on the Bank itself (station M). Respiration was measured using an oxygen gradient technique<sup>6</sup>. Samples (10 ml) were pipetted into polycarbonate filter manifolds and filtered through 2- $\mu$ m Nuclepore filters. The same volume of filter-sterilized (0.2- $\mu$ m filtered) sea water was then added to each manifold and oxygen gradients were measured at *in situ* temperature to a distance of 5 mm above the material collected on the surface of each filter. The gradients allowed calculation of the downward flux of oxygen over a given length of time and thus the rate of consumption per cm<sup>2</sup> of surface or per ml of original sample. Error bars from selected triplicate incubations were all smaller than the dimensions of the symbols.

surface coagulation<sup>5</sup>. Physical models of the mass transfer of organic particles in turbulence<sup>10</sup> show that colloids of about 1  $\mu$ m in diameter are situated at the boundary between two domains of mass transfer. Particles smaller than 1  $\mu$ m are more rapidly transported to bacterial cells by convective diffusion, whereas larger particles are more effectively transported by collision with cells in turbulent shear. In effect, there appears to be an untapped reservoir of labile organic carbon that is not easily accessed by bacteria in the absence of surface coagulation. This in turn leads to an obvious but important conclusion. The interpretation of data from experiments designed to illustrate the microbial effects of bubbling will be seriously compromised if colloidal organic material has been removed by filtering.

FIG. 2 Respiration in bubbled sea waters (open circles) and unbubbled controls (closed circles) from four depths at a station occupied for 9 days in the Sargasso Sea (at 36° 00'N; 64° 05'W). During this time, the mixed layer of surface water extended down to a depth of 60–70 m. Error bars from selected triplicate incubations were all smaller than the dimensions of the symbols.

On Georges Bank, the mean respiration in unbubbled controls increased (Fig. 1; Table 1) as the environment at a depth of 10 m progressed from the mixed layer of a stratified water column in the Fundian Channel (station 21) to a tidal front at the edge of the Bank (stations 2 and 3) and finally to well mixed, particle-rich water on the Bank itself (station M). Respiration was enhanced by surface coagulation to approximately the same absolute value at all 4 stations but, when compared with the controls, enhancement decreased by over an order of magnitude from station 21 to station M (Table 1). The reduced effect of surface coagulation in well mixed water at station M (ref. 11) was probably related to increased respiration of labile organics coagulated with larger numbers of suspended particles (1.1 p.p.m. at station M compared with 0.2 p.p.m. at station 21; P.E.K. and D.K. Muschenheim, unpublished observations). As a result, the effects of bubbling and surface coagulation may be of greater biological significance in sea water with low concentrations of suspended particulates, such as that found at station 21.

Bubbling enhanced respiration by a factor of 4.8–11.2 in the Sargasso Sea (Fig. 2; Table 1). This enhancement was positively correlated with primary production (Fig. 3) and decreased rapidly below the base of the mixed layer at 60–70 m (Fig. 2). Surface coagulation in this particle-poor environment may therefore be confined in its biological effect to relatively 'new' colloids associated with primary production in the upper ocean. The reasons why surface coagulation caused such a rapid microbial response are not clear, but the answer may lie in the results of Baylor *et al.*<sup>12</sup> and Graham *et al.*<sup>13</sup>, which show that bubbling sea water for 18–45 min can concentrate phosphorus into the adsorbed or coagulated phase by a factor of 4 to 200. Given that microbial growth is probably not carbon-limited in surface waters<sup>14</sup>, the degree to which nutrients such as phosphorus and nitrogen are involved in surface coagulation may ultimately regulate the magnitude of a microbial response to aggregate generation.

It still remains to be seen if bubble spectra in a glass column are typical of those found under a breaking wave, but it is our experience that data from bubbling columns may underestimate, rather than overestimate, the physical and biological effects of surface coagulation. A bubbling column can appreciably enhance the transport of 1 µm colloids to bacteria, but models of mass transfer of the same material by natural bubble populations under breaking waves<sup>10</sup> indicate that the enhancement may

Respiration in the unbubbled controls fell within the range of values from earlier work and respiration in many of the bubbled sea waters exceeded the range of values from earlier work. The systematic variations in respiration that we observed in the presence or absence of bubbling may therefore have already been observed in earlier studies as apparently random variations. See ref. 20 for previous measurements.

\* Mean respiration in the bubbling experiments was calculated from 8 or 9 oxygen consumption rates measured over a 32-h period.

† The enhancement of respiration was calculated from mean respiration (bubbled) divided by the mean respiration from an equivalent unbubbled control.

FIG. 3 Linear correlation of the enhancement of mean respiration by surface coagulation (Table 1) and *in situ* primary production at four depths in the Sargasso Sea (W. G. Harrison and B. Irwin, unpublished results). The equation of the line best fitting the data is  $y = 2.3 + 23.8x$  ( $r = 0.99$ ).

be too low by a factor of 2–20. This reinforces the concept that a substantial fraction of labile DOC may escape degradation by virtue of its particle size characteristics, and that surface coagulation is required to make the carbon available to bacteria.

The rapid respiratory responses in Figs 1 and 2 leave no doubt that the aggregates produced by coagulation are labile. When cumulative oxygen uptake was calculated from consumption rates on Georges Bank, 10–13  $\mu\text{mol O}_2 \text{ l}^{-1}$  were consumed over 32 h in bubbled sea waters from 10 m. This was equivalent to the respiration of 0.12–0.16  $\text{mg C l}^{-1}$ , or 10–15% of the 1.1  $\text{mg C l}^{-1}$  of DOC available for coagulation, as estimated from DOC analyses using the ultraviolet oxidation technique of Cauwet<sup>15</sup> (P.E.K., unpublished results). There is some uncertainty<sup>16,17</sup> and controversy<sup>18</sup> involved in the interpretation of DOC measurements in sea water, but the respiration of 10–15% of a given DOC pool in as little as 32 h indicates that significant quantities of carbon could be made available to the biota by surface coagulation. Even if the measurement controversy is resolved and there is more DOC than was previously thought in the upper ocean<sup>17</sup>, there is still a wide variation in the quantity of material coagulated by bubbling. Only 5% of the DOC pool (0.035  $\text{mg C l}^{-1}$  from a pool size of 0.7  $\text{mg C l}^{-1}$ ; P.E.K., unpublished results) was respired over 32 h when Sargasso sea water from 10 m was bubbled. Although this was 2–4 times lower than the carbon respired at the same depth on Georges Bank, primary production (4.5  $\mu\text{g C l}^{-1} \text{ d}^{-1}$  compared with 50–400  $\mu\text{g C l}^{-1} \text{ d}^{-1}$  on Georges Bank; W. G. Harrison and B. Irwin, unpublished results) was 12–88 times lower. This means that the physical regeneration of organic material by coagulation on bubble surfaces may have a more pronounced effect on microbial communities in regions of low productivity like the Sargasso Sea.

The results obtained when sea water from 10 m in Bedford Basin, Halifax Harbour (Canada) was bubbled during June 1988 (Table 1) demonstrate that respiration in a coastal environment can be enhanced by a factor within the range of values from the open ocean. More importantly, bacterial counts by epifluorescence<sup>19</sup> showed that a rapid increase in bacterial number (to values as high as  $16 \times 10^6 \text{ cells ml}^{-1}$ ) was associated with the respiration induced by surface coagulation. Bacterial growth was then followed by a decline as protozoan numbers increased, and the end result of 32 h of intense microbial activity was a relatively low number of bacteria ( $1.6 \times 10^6 \text{ cells ml}^{-1}$ ). Thus, when different amounts and different fractions of DOC are made available as different sea waters are bubbled, the rapidity of the biological response to surface coagulation is a common factor which cannot be ignored. The coagulation of DOC by bubbling may well be an important oceanographic process in its own right<sup>5,10</sup> but, when combined with rapid respiration of the coagulated material, it could also be a mechanism for recycling a globally important reservoir of carbon<sup>1</sup> back to  $\text{CO}_2$  in the upper ocean. □

## Developmental failure and loss of reproductive capacity in the rare palaeoendemic shrub *Dedeckera eurekensis*

EVOLUTIONARILY successful outcrossing plants have spontaneous seed sets that are, on average, around 50% ( $\pm 20\%$ ), but those of woody species are lower (33%) and herbaceous perennials higher (57%); self-pollinating (autogamous) species average about 85%<sup>1–3</sup>. *Dedeckera*, an outcrossing (protandrous) evolutionary relict from the Mojave desert of California has a seed set of only 2.5% and no means of vegetative reproduction. We show here that the most probable explanation for this exceptional result is that there are genetically mediated embryonic abnormalities. The percentage of fully viable seeds is further reduced by low viability, germinability, and post-germination developmental failure. Genetic studies involving extinction have emphasized inbreeding depression and homozygosity<sup>4–8</sup>, but *Dedeckera* is highly heterozygous (27%). Outcrossing does not significantly increase seed set over selfing, suggesting that a high segregational genetic load is primarily responsible for the low seed set in *Dedeckera*. Such loss of reproductive capacity could explain the relictual nature of *Dedeckera* and might ultimately result in its extinction.

A histological analysis of post-fertilization development of 27 ovules of *Dedeckera* showed a pattern of genetically controlled embryo abortion similar to that reported in *Epilobium*<sup>3</sup> (Onagraceae), and *Arabidopsis*<sup>9,10</sup> (Brassicaceae), and in species hybrids<sup>11</sup>. Three ovules showed no evidence of fertilization.

Spontaneous seed germination in seven trials was only 3.5% ( $N = 460$  filled seeds). Sixty days of stratification had no effect, but scarification and gibberellic acid treatment increased germination to 33%. Only 11.1% of spontaneously germinating seeds

‡ Deceased.

developed normally, but the sample size was small ( $N=9$ ). Thus the percentage of fully viable seeds in *Dedeckera* is probably less than 0.5%. *Dedeckera* may produce about 64,500 flowers and ovules (ovaries are uniovulate). Given seedling survivorship values for desert perennials<sup>12,13</sup> of  $10^{-4}$  to  $10^{-5}$ , the loss of reproductive capacity in *Dedeckera* may be critical for its continued survival.

Neither prezygotic genetic self-incompatibility nor inadequate pollination explain the exceptionally low fecundity of *Dedeckera* because about 90% of the ovaries initiate growth, which is taken as *prima facie* evidence for fertilization (Table 1). The consistency of the data, both between populations and in different years, indicates that resources do not limit seed set (Table 1), and also argues against gametic imbalance and hybrid dysgenesis as explanations for low seed set. *Dedeckera* is not a chromosome translocation heterozygote ( $n$  is about 12 bivalents). Herbivory was uncommon and there was no overt evidence of pathogen activity.

Intraplant self-pollination (geitonogamy) may be common in *Dedeckera*<sup>14</sup>, but inbreeding depression resulting from selfing in a normally outcrossed population (segregational genetic load) is not a major factor contributing to the low seed set (Table 2). The seed set for controlled self-pollinations (6.3%) and cross-pollinations (11.4%) do not differ significantly ( $d.f.=1$ ,  $\chi^2=2.95$ ,  $P>0.05$ ) and all population sizes exceed 150 (Table 2).

Allozyme analyses were completed from each of the six populations studied (Table 1) to determine the amount of genetic polymorphism and heterozygosity.  $F$ -statistics<sup>15</sup> were used to examine apportionment of variation within and between populations. Mean values, summed for all populations, are  $F_{IS}=0.192$ ,  $F_{IT}=0.299$  and  $F_{ST}=0.133$ , which indicate that there is a limited degree of interpopulational differentiation with most variance residing within populations.

Polymorphism over 17 loci and six populations is 56.8%. Heterozygosity averaged over the subset of the 12 polymorphic loci is 26.9% (Table 3). Heterozygotes range from 11.9% for

The structures scored are anatomically indehiscent, single-seeded, post-anthesis ovaries or maturing fruits (achenes), although functionally they behave essentially as seeds. Developed (aborted) fruits reach approximately full length, but the ovary wall is partially collapsed between the ribs and the ovule has atrophied. Partially developed fruits did not reach full size, but all initiated ovary expansion before ovule abortion, which is taken as *prima facie* evidence for fertilization. Non-developed ovaries showed no evidence of expansion. They were probably not pollinated, or the ovules were unfertilized, or abortion occurred at the earliest stages of embryogenesis or endosperm development.

Flowers isolated in nylon enclosures	3.9	26.0	65.5	4.6	281	3

Coldwater Canyon population, 2-29 July 1988 (see Table 1 legend for locality and explanation of fruit types). Control flowers were taken from unmanipulated portions of experimental plants and left open so that pollination was spontaneous. Isolated flowers were those simply left under nylon enclosures (after removing all open or fruiting flowers), thus excluding all insect pollen vectors. All open or fruiting flowers were removed from the experimental inflorescences after which they were enclosed with removable fine-mesh nylon covers mounted over a wire frame to prevent contact of the nylon with the flowers. Flowers were emasculated daily before anthesis. All three stigmas were pollinated by contacting their sticky surfaces with a dehiscing anther after the styles had diverged and the stigmas became receptive. The small flowers (2-3 mm) required that all floral manipulations be effected under a dissecting microscope mounted on a camera tripod. The nylon covers were removed after the completion of all pollinations.

TABLE 3 Genetic variability at 12 loci

	Mean sample size per locus	Mean no. of alleles per locus	% Loci polymorphic	Mean heterozygosity
White Mountains populations				
Bishop	15.8	1.9	66.7	0.211

Last Chance Mountains populations				
Dedeckera Cyn (upper)	14.8	2.7	91.7	0.384
Dedeckera Cyn (lower)	16.7	3.3	91.7	0.293
Last Chance Mts	13.3	2.7	83.3	0.318
Means	14.9	2.9	88.9	0.332

Values in this table are derived from analysis of 12 loci—EST-2 (esterase), GSR-2 (glutathione reductase), IDH-2 (isocitrate dehydrogenase), MDH-1, MDH-2, MDH-4 (malate dehydrogenase), MDR-1 (menadione reductase), GPI-2 (glucose phosphate isomerase), PGM-1, PGM-2, PGM-3 (phosphoglucosmutase) and SKDH (shikimate dehydrogenase)—that were polymorphic in at least one of the six populations. When five additional loci ADK-1 (adenylate kinase), GPI-1, GSR-1, LAP (leucine amino peptidase), and MDH-3, monomorphic for all populations, are included, the mean polymorphism is 56.8%. A locus was considered polymorphic if any allelic variant was detected. Mean proportion of heterozygotes (direct count) is less than the expected Hardy-Weinberg (unbiased estimate)<sup>24</sup>. The fixation index  $F^{25}$  showed that only two loci (PGM-1 in the Gunter Cyn population and SKDH in the population of the Last Chance Mountains) had significant ( $P < 0.001$ ) deviations in genotype proportions.

MDR-1 to 58.3% for GPI-2. These heterozygosity averages are underestimated because they include the zero values for those markers that are not polymorphic in the particular population sampled. This amount of variation is much higher than that reported for other species of desert shrubs<sup>16</sup>, but is similar to other woody, outcrossing perennials<sup>17-18</sup>.

*Dedeckera* is vegetatively vigorous and flowers profusely. Its longevity (at least 140 years and probably much more) may be correlated with heterozygosity as reported in *Liatris*<sup>19</sup> (Asteraceae). In *Dedeckera*, vegetative fitness may be largely dependent upon rare, highly heterotic (or possibly epistatic) genotypes. The uniquely heterozygous genotypes that do survive may, however, have low reproductive potential because of the excessively high segregational genetic load. Reproduction could be further compromised by the accumulation of recessive lethals in long-lived meristems<sup>20</sup> and chromosomal mutations<sup>21</sup>.

The persistence of palaeoendemics may depend on rare multiple-locus heterotic genotypes that could arise as a result of tracking some protracted secular environmental change, for example, increasing aridity. The pace and extent of such change could easily exhaust the species' additive genetic variance relevant to adapting to that change. Heterosis may be the only survival strategy available to such species, in spite of the negative reproductive consequences. Thus the 13% increase in mean heterozygosity for the populations of *Dedeckera* in the Last Chance Mountains, as opposed to those in the White Mountains (Table 3), may be important because the former localities are both hotter and drier. In fact, many palaeoendemics may be ecologically 'out of place', in that they may not possess many of the adaptations typical of plants occupying that habitat—thus *Dedeckera* flowers in mid-summer when desert perennials are typically dormant.

Rabbits<sup>22</sup> and humans<sup>23</sup> have genetically mediated spontaneous embryo abortion rates of about 50% and 70%, respectively. The loss of reproductive capacity stemming from early embryonic genetic load should not be overlooked as a possible element in the decline of higher animal palaeoendemics. Such cases may be observed rarely because higher animals generally have much shorter life-spans, relatively limited reproductive potentials, and because early abortion is more difficult to detect than in plants.

Other palaeoendemic plants in North America, Africa and Australia also seem to have exceedingly low seed sets. Reproductive capacity should be given careful consideration in management decisions regarding rare and/or endangered species. □

ACKNOWLEDGEMENTS. We thank J. Chesnut, J. Neuhauser, M. Kobler, S. Wroe, W. Owen, O. Pollak, C. Scheidinger, S. Hodges and M. Weiss for field and laboratory assistance, and the staff of the White Mountain Research Station, Bishop, California, for laboratory facilities. J. Ehleringer, T. Hazelrigg, D. Mansfield, K. Paige, P. Raven, R. K. Vickery Jr, E. O. Wilson, and especially J. Endler, have read and commented on the manuscript. M. DeDecker, J. Dickinson and W. Wiens offered various suggestions. J. Rourke first mentioned the existence of plants with exceptionally low sexual reproductive capacity in Africa. The study was supported by grants from the NSF, the USDA (Forest Service, Rocky Mountain Forest and Range Experiment Station) and the University of Utah, College of Science.

## The *ninaA* gene required for visual transduction in *Drosophila* encodes a homologue of cyclosporin A-binding protein

Bi-Hwa Shieh, Mark A. Stamnes, Suzanne Seavello, Greg L. Harris & Charles S. Zuker

Department of Biology and Center for Molecular Genetics, University of California, San Diego, La Jolla, California 92093, USA

MUTATIONS of the *Drosophila melanogaster ninaA* gene affect phototransduction: *ninaA* mutant flies have a 10-fold reduction in the levels of rhodopsin in the R1–R6 photoreceptor cells<sup>1,2</sup>. The *ninaA* gene was isolated and found to encode a 237-amino-acid protein that has over 40% amino-acid sequence identity with the vertebrate cyclosporin A-binding protein, cyclophilin, a protein that seems to be involved in T-lymphocyte activation. The remarkable evolutionary conservation of cyclophilin in two phylogenetically distant organisms and its involvement in diverse transduction processes suggests that this protein plays an important role in cellular metabolism. Indeed, cyclophilin has recently been shown to be a prolyl *cis-trans* isomerase that catalyses, *in vitro*, rate-limiting steps in the folding of a number of proteins<sup>3,23</sup>. Here, we present evidence for the involvement of cyclophilin-like molecules in a defined cellular process. The availability of mutations in a cyclophilin gene provides a new model system for the study of cyclophilin and cyclosporin action.

Numerous mutations that affect visual transduction in *Drosophila* have been isolated (reviewed in refs 4, 5). To isolate genes encoding phototransduction-specific proteins, we used a subtractive hybridization protocol to identify genomic clones

containing sequences preferentially expressed in the adult visual system. Clones that tested positive in our screen (see Fig. 2 legend) were isolated and used in *in situ* hybridizations to polytene chromosomes to determine their cytogenetic map positions. The *ninaA* locus has been mapped to the second chromosome, position 21D3-E2 (ref. 1). Two of the 120 genomic clones we isolated,  $\lambda$ 322 and  $\lambda$ N4, were mapped to position 21D4-E2, within the cytogenetic map location of *ninaA*. The *ninaA* locus constitutes one of eight complementation groups of *Drosophila* mutants with drastically reduced rhodopsin levels<sup>1,2</sup>. *ninaA* flies have a severe reduction of rhodopsin (Rh1) levels in the R1-R6 photoreceptor cells (Fig. 1). The reduction of rhodopsin levels in the R1-R6 photoreceptors of *ninaA* mutant flies has recently been shown<sup>6</sup> not to be due to reduced expression of the R1-R6 opsin gene (*ninaE*) but may be the result of a defect in some aspect of post-translational processing of the *ninaE* opsin, or a secondary effect on the stability of rhodopsin due to a defect in phototransduction.

Characterization of clones  $\lambda$ 322 and  $\lambda$ N4 showed that they contain overlapping sequences and encode a 0.9 kilobase (kb) RNA (Fig. 2) that is present in preparations of poly (A)<sup>+</sup> RNA from wild-type heads, but not from wild-type bodies or heads from mutant flies lacking the compound eyes (*eya*; eyes absent<sup>7</sup>) (Fig. 2b). We used the large *Eco*RI restriction fragment of  $\lambda$ 322 to screen a *Drosophila* head cDNA library and isolated several cDNA clones. Using M13 dideoxynucleoside triphosphate sequencing we have determined the DNA sequence of one of those cDNA clones and of the 1.2 kb *Hind*III-*Pst*I genomic fragment of  $\lambda$ 322 (Fig. 2a). Figure 3a shows the nucleotide sequence and the deduced amino-acid sequence of the *ninaA* gene product. The structure of the RNA (Fig. 2a) was determined by analysing genomic and cDNA sequences. Confirmation that  $\lambda$ 322 includes the *ninaA* gene was obtained by determining the nucleotide sequence of the *ninaA*<sup>P228</sup> mutant allele. Transcript size and levels are normal in these mutant flies (Fig. 2b). The mutant allele was isolated and cloned by a polymerase chain reaction. The *ninaA*<sup>P228</sup> allele has all the nucleotide sequence polymorphisms of the Oregon-R strain. Interestingly, however, this allele has a single coding nucleotide change at position 895, from TGG to TGA, causing a change from the encoded tryptophan to an opal translation termination codon (Fig. 3a arrow). The nature of this change is consistent with the chemical mutagenic origin of *ninaA*<sup>P228</sup> (ref. 1). Thus, the cytogenetic location, expression profile, and altered nucleotide sequence in mutant flies are all consistent with this being the *ninaA* gene.

Comparison of the deduced amino-acid sequence of *ninaA* with previously sequenced genes and proteins revealed very high homology to the bovine cyclosporin A-binding protein cyclophilin (Fig. 3b). These two proteins have more than 40% amino-acid identity throughout their length (shaded boxes); conserved

FIG. 1 *ninaA* mutants have a severe reduction of Rh1 opsin levels. Protein extracts were prepared from the heads of control and *ninaA* flies by digitonin extraction<sup>23</sup>. Serial dilutions (0.25, 0.5, 1, 2 and 4  $\mu$ g) were slot-blotted onto nitrocellulose paper and processed for western analysis using a monoclonal antibody against the Rh1 opsin (kindly provided by Dr H. Gert de Couet). Mutant flies have a 8–10-fold reduction of the opsin present in the R1–R6 photoreceptors (Rh1). The right panel shows similar extracts (4, 2 and 1  $\mu$ g) treated with a monoclonal antibody against the ocellar (Rh2) opsin. This monoclonal antibody was generated against a Rh2-specific synthetic peptide. Note the specificity of the mutant phenotype for the Rh1 opsin (see also refs 1, 2).

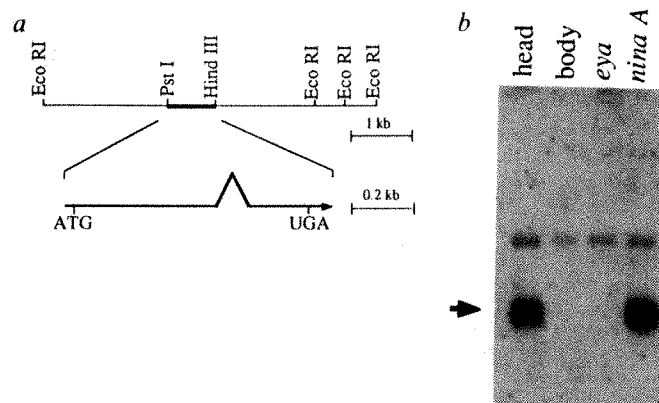

FIG. 2  $\lambda$ 322 encodes an eye-specific transcript. a, Restriction map of  $\lambda$ 322 and structure of the RNA it encodes. A map of  $\lambda$ 322 indicating the restriction sites for *Hind*III, *Pst*I and *Eco*RI (top map). The diagram below the map shows the structure of the RNA as deduced by comparison of the nucleotide sequence of a cDNA clone and the genomic sequence. b, Poly (A)<sup>+</sup> RNAs were extracted from adult heads of wild-type, *eya* and *ninaA* flies and from adult bodies. The RNAs (3  $\mu$ g per lane) were gel-fractionated, blotted, and hybridized to a 1.2-kb  $\lambda$ 322 radiolabelled *Pst*I-*Hind*III fragment.  $\lambda$ 322 hybridizes to a 0.9-kb eye-specific transcript (arrow). The blot was also hybridized to a probe encoding 'common' RNAs to control for the amount of RNA loaded ( $\lambda$ 9, unpublished observations). Hybridization to  $\lambda$ 9 mRNA is seen as the band present in all lanes with a mobility significantly slower than  $\lambda$ 322 mRNA. An RNA ladder (BRL) was used to provide size markers.

METHODS.  $\lambda$ 322 was isolated by hybridization with eye-specific probes. Poly (A)<sup>+</sup> RNA, isolated from the heads of wild-type flies, was used to template the synthesis of cDNA. This cDNA was hybridized in solution to a 20-fold excess of poly(A)<sup>+</sup> RNA isolated from the bodies of adult flies. Single-stranded molecules were then separated from the double-stranded DNA:RNA heteroduplexes by hydroxylapatite chromatography<sup>24</sup>. Hybridizations were carried out in 30  $\mu$ l of 0.5 M phosphate buffer (pH 6.9) containing 2  $\mu$ g of head cDNA and 40  $\mu$ g of body RNA. The reaction mixtures were incubated for 24 h at 65 °C. The resulting single-stranded cDNA, representing mostly 'head-specific' sequences, were used in a second round of subtraction with RNA isolated from heads of flies carrying the *eya* mutation<sup>7</sup>. Single-stranded molecules were fractionated by hydroxylapatite chromatography and used as templates for the synthesis of very high specific activity second-strand cDNA by two rounds of amplification with random primers (pN<sub>6</sub>, Amersham). This radiolabelled cDNA, representing a probe highly enriched in eye-specific sequences, was then used to screen a genomic library. Subtractions with *eya* head poly(A)<sup>+</sup> RNA were carried out with 0.2  $\mu$ g of head-enriched cDNA and 4  $\mu$ g of *eya* RNA. About 10% of input cDNA was recovered after the first subtraction, and about 20% after the second. First and second-strand cDNA synthesis were carried out as described<sup>25</sup>.

substitutions account for over 30% of the remaining amino-acid residues. Cyclophilin is a soluble protein with a relative molecular mass ( $M_r$ ) of 17,000 with high binding affinity and stereospecificity for cyclosporin A (CsA)<sup>8–11</sup>. CsA is an 11-amino-acid cyclic peptide of fungal origin with potent immunosuppressive properties widely used to prevent graft rejection and for the treatment of autoimmune disorders (reviewed in refs 12–14). Recent data support the hypothesis that the action of CsA is mediated through cyclophilin<sup>15–17</sup>. Although the exact mechanism of CsA action is not known, there is good evidence from whole cell systems that CsA interrupts an early event in the antigenic activation of T helper cells that results in lymphokine production<sup>18–20</sup>.

To determine whether *Drosophila* does indeed contain proteins with CsA-binding activity, we carried out [<sup>3</sup>H]CsA binding assays on head extracts prepared from wild-type controls, *eya*, and *ninaA*<sup>P228</sup> flies. As shown in Fig. 4, head extracts have significant levels of cyclophilin-like activity (specific partition on sepharose LH-20 chromatography<sup>8–11</sup>); about 30% of the head binding is associated with the visual system in that it is removed by the *eya* mutation. The *ninaA*<sup>P228</sup> mutation leads to a similar decrease in CsA binding indicating that the *ninaA*

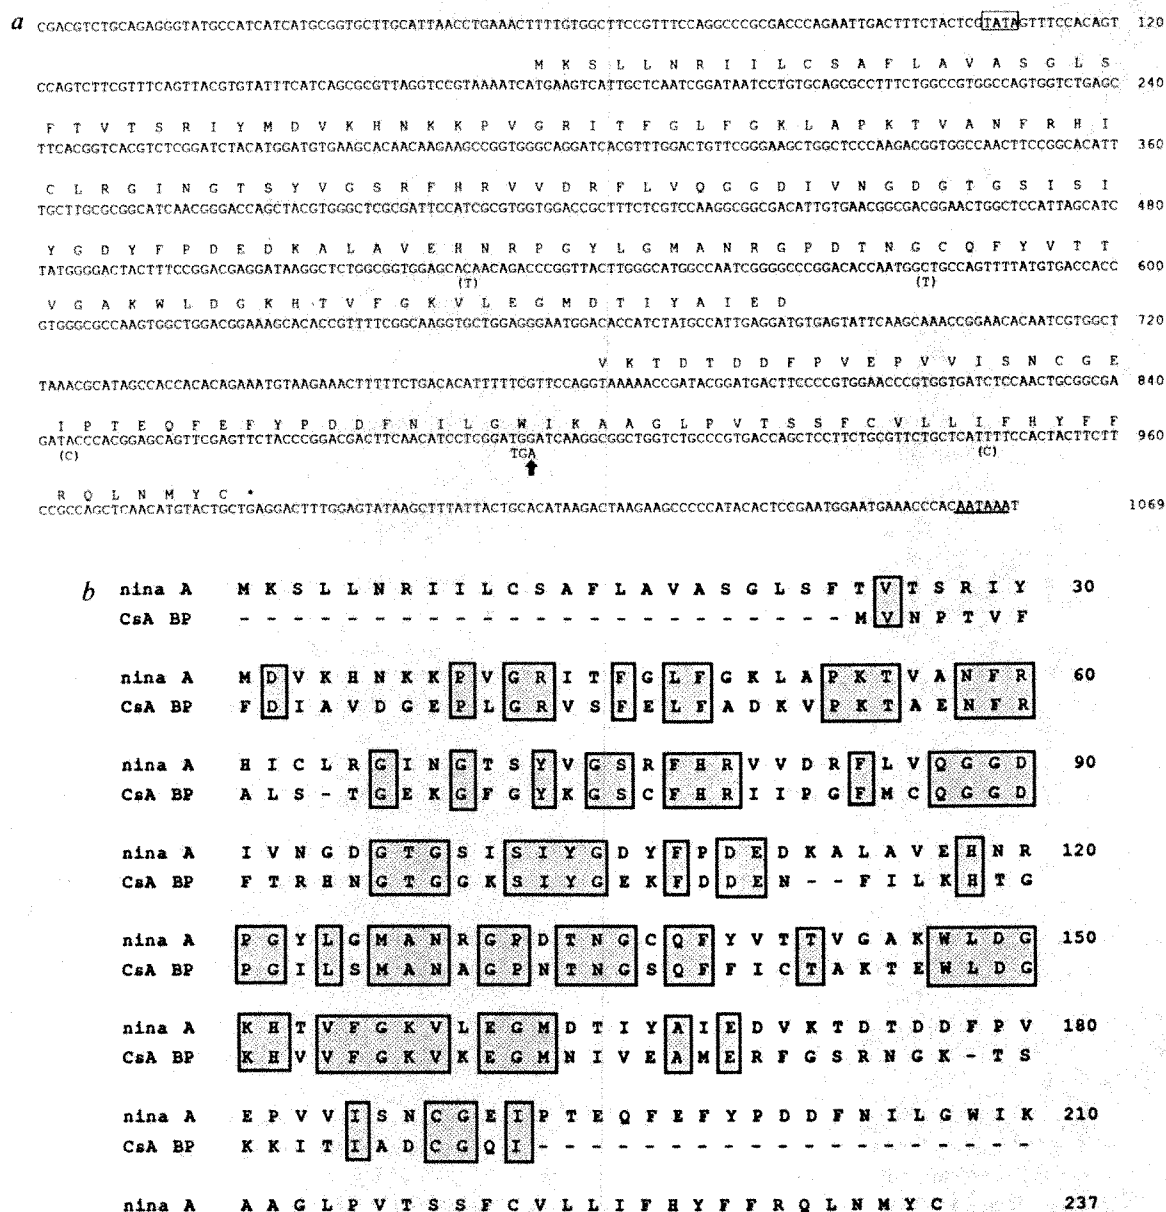

FIG. 3 Nucleotide sequence and deduced amino-acid sequence of the *ninaA* gene. **a**, The sequence shown was determined on both strands of the genomic and cDNA clones<sup>26</sup>. The boxed region at positions 106–110 shows the putative TATA box. The putative polyadenylation signal is underlined at positions 1,063–1,068. The deduced protein sequence is shown aligned under the nucleotide sequence. The initiator methionine was assigned as the first in-frame methionine in the sequence. The gap at nucleotides 686–782 indicate the presence of a 96-base pair (bp) intron. The arrow at position 895 highlights the single nucleotide change in the *ninaA*<sup>P228</sup> mutant gene (G→A). This change creates a translation termination codon. The single nucleotides below positions 528, 579, 844 and 946 show the differences in the coding regions between the cDNA (Oregon R, P2 strain) and the genomic (Canton S) sequence; none of these polymorphisms would result in a change in the encoded amino

acid. **b**, A co-linear alignment of the deduced amino-acid sequence of the *ninaA* gene and the bovine cyclophilin protein<sup>10</sup>. Cyclophilin from mammalian species analysed so far have over 95% sequence identity, and the physical properties of the CsA binding proteins from other vertebrate species are remarkably similar<sup>10,27,28</sup>. Amino acids are designated by the single-letter code. The alignment has been optimized for the largest number of identities with the least number of gaps. Boxed areas indicate the amino-acid identities between the two proteins.

**METHODS.** The mutant allele was cloned by selective amplification of the *ninaA* gene by polymerase chain reaction using protocol and reagents supplied by Perkin-Elmer Inc. (PCR kit N801-0043). Oligonucleotides complementary to positions –8 to +11 and +986 to +1,005 were used as primers.

locus encodes a cyclophilin-like protein that accounts for most of the visual system-specific CsA-binding activity (Fig. 4). The binding activity remaining in the *eya* and *ninaA* extracts probably represents the presence of non-eye-specific cyclophilin-like proteins.

The *ninaA* R1–R6 photoreceptors have about 10% of wild-type levels of rhodopsin<sup>1,2</sup>. Zuker and co-workers<sup>6</sup> have previously shown that the Rh1 opsin gene is expressed at normal levels in *ninaA* mutants. The reduction of rhodopsin must therefore be a post-transcriptional or a post-translational event. The discovery that cyclophilin encodes a prolyl *cis-trans* isomerase<sup>3</sup>

suggests that it may be required for the correct folding of proline-containing polypeptides. We propose that this isomerase activity is necessary for the correct folding and the stability of rhodopsin in *Drosophila* R1–R6 photoreceptors. The requirement for large amounts of rhodopsin in these cells may explain the existence of a photoreceptor cell-specific form of this enzyme. Moreover, the existence of a cell-specific isoform suggests that there are specific substrates for these proteins and explains the presumed diversity of cyclophilin-like molecules (M.A.S. and C.S.Z., unpublished observations and refs 3, 10). It is therefore possible that, in the immune system, CsA blocks

FIG. 4 *ninaA* flies have reduced levels of cyclosporin A-binding activity. Extracts prepared from heads of control *w*<sup>1118</sup> flies, *eya* or *ninaA* flies were tested for CsA-binding activity<sup>9</sup>. The results indicate that *Drosophila* head extracts contain significant amounts of cyclophilin-like activity (approximately 30 ng CsA binding mg<sup>-1</sup> extract) and that all eye-associated binding is reduced in *ninaA* flies (compare *eya* and *ninaA* extracts). Bars above the graph indicate standard errors (*w*<sup>1118</sup>, *n*=10; *eya*, *n*=8; *ninaA*<sup>P228</sup>, *n*=7). *Drosophila* extracts were prepared from heads of wild-type or mutant individuals exactly as described<sup>9</sup>. Binding assays were carried out with <sup>3</sup>H-cyclosporin A (17 Ci mmol<sup>-1</sup> Amersham) at either 30 °C or 37 °C and the products separated by partition chromatography on a Sephadex LH-20 column<sup>8</sup>. The inset shows the specificity of the binding assay as determined by competition with unlabelled CsA.

the activity of a cyclophilin required for the proper functioning of the antigen-mediated transduction pathway.

In the visual system, the interconversion between the active (metarhodopsin) and inactive (rhodopsin) states of the visual pigment molecule involves significant conformational changes. In the invertebrate visual cascade, these two forms are thermally stable and photoconvertible. It would therefore be very interesting to determine whether the isomerase encoded by *ninaA* is important in this event during the transduction cycle. The availability of *Drosophila* lines carrying mutations in the endogenous *ninaA* gene, and the use of P-element-mediated germline transformations<sup>21,22</sup>, may allow for the functional expression of wild-type and modified alleles in their normal cellular and organismal environment. A combined biochemical, physiological and molecular genetic dissection will help assign specific roles to the *ninaA* gene product in the phototransduction process. □

\*Laboratory of Molecular Microbiology, National Institute of Allergy and Infectious Diseases, NIH, Bethesda, Maryland 20892, USA

MUTANT mice homozygous for 'retinal degeneration slow' (*rds/rds*) are characterized phenotypically by abnormal development of photoreceptor outer segments in the retina, followed by gradual degeneration of photoreceptors<sup>1–3</sup>. This process of degeneration is complete by one year, with preservation of all other retinal cells<sup>4</sup>. The biochemical defect that leads to the mutant phenotype is not known. Our strategy for cloning the *rds* gene was based upon three previously reported observations. First, the *rds* locus maps to chromosome 17<sup>5,6</sup>. Second, experimental *rds/rds* ↔ +/+ and *rds*/+ ↔ +/+ tetra-parental mice manifest patchy photoreceptor changes in the retina<sup>7,8</sup>, suggesting that the wild-type *rds* locus is expressed within cells of the photoreceptor lineage. Finally, the process of degeneration is specific to photoreceptors. On the basis of these observations, we predicted that the *rds* mRNA is encoded by a gene on chromosome 17 and is normally expressed exclusively within photoreceptors in the retina. We here present evidence that this is the case.

Given our predictions, a cDNA representing a photoreceptor-specific mRNA encoded by a gene on chromosome 17 would be a candidate clone of the *rds* mRNA. To isolate cDNA clones of photoreceptor-specific mRNAs, we took advantage of the unrelated mouse mutant, retinal degeneration (*rd/rd*)<sup>9,10</sup>. Mice homozygous for this mutation manifest rapid degeneration of photoreceptors, a process that is virtually complete by four weeks, with the preservation of all other retinal cell types<sup>11,12</sup>. Therefore, an mRNA present in wild-type (C57BL/6) but absent from fully degenerate *rd/rd* (C3H/HeJ) retina is photoreceptor-specific. cDNA clones of twelve different photoreceptor-specific mRNAs were isolated from an adult C57BL/6 mouse retina library by subtractive and differential colony screening<sup>13</sup> of 6–7-week-old C57BL/6 minus 6–7-week-old C3H/HeJ retina. Northern blot hybridization patterns for six of these clones are shown in Fig. 1a.

The chromosome assignments for the genes encoding each of the 12 photoreceptor-specific mRNAs were made by probing a panel of mouse × hamster hybrid cell-line DNAs<sup>14</sup> with a representative clone of each of the photoreceptor-specific mRNAs. Clone IG3 mapped to chromosome 17 with 100% concordance

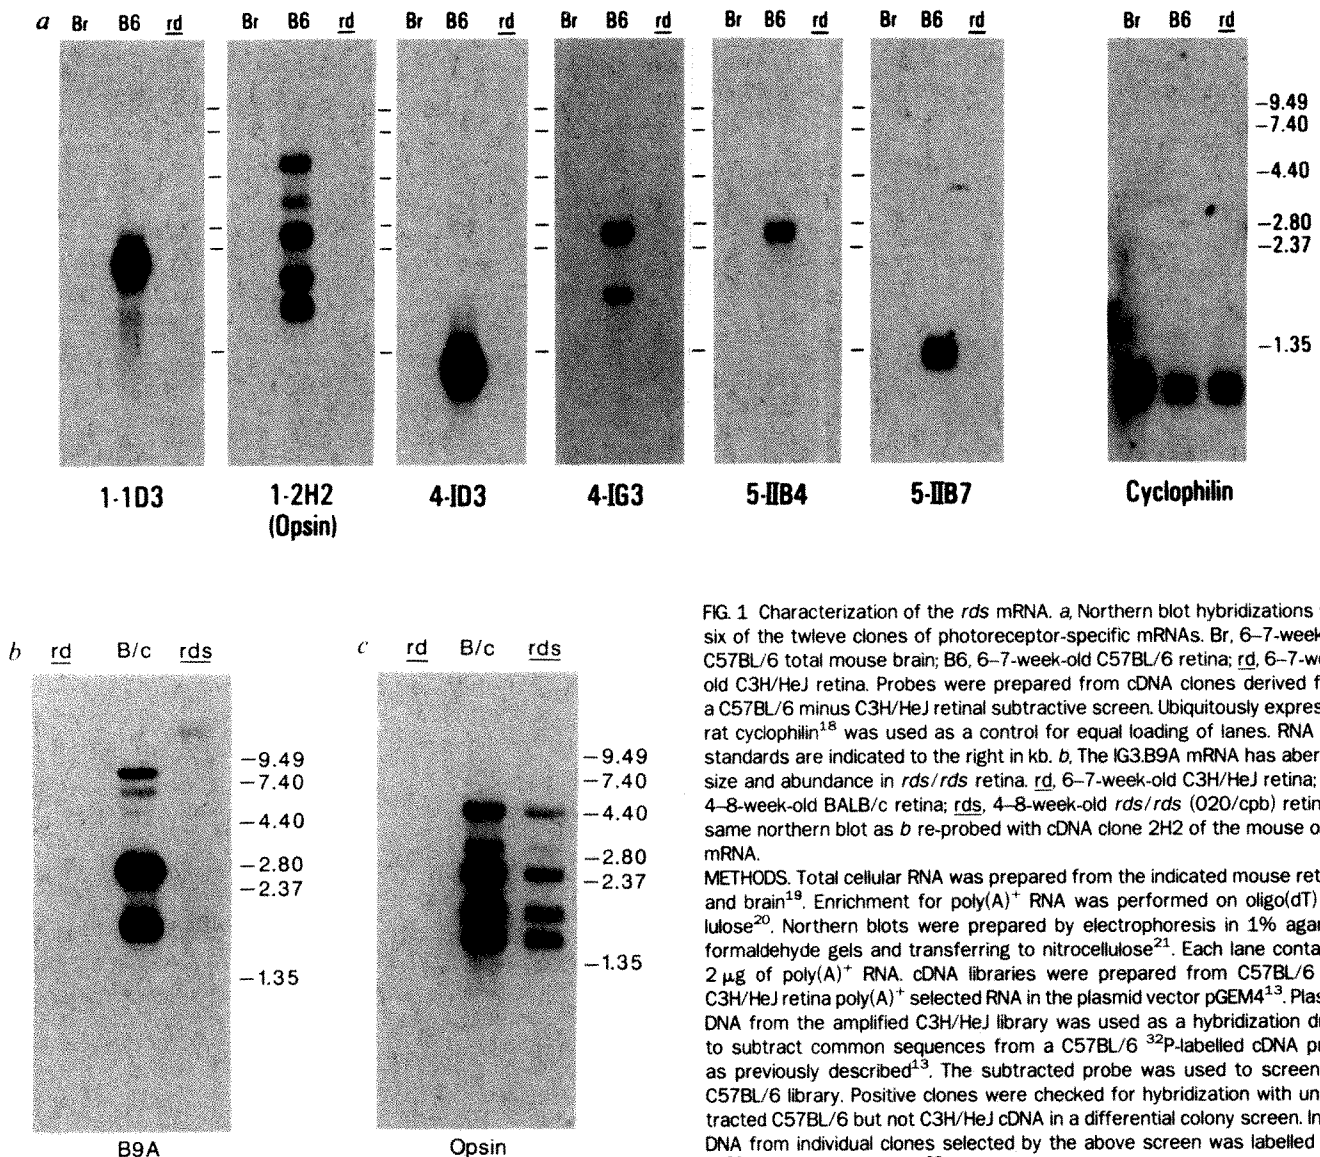

FIG. 1 Characterization of the *rds* mRNA. **a**, Northern blot hybridizations with six of the twelve clones of photoreceptor-specific mRNAs. Br, 6–7-week-old C57BL/6 total mouse brain; B6, 6–7-week-old C57BL/6 retina; rd, 6–7-week-old C3H/HeJ retina. Probes were prepared from cDNA clones derived from a C57BL/6 minus C3H/HeJ retinal subtractive screen. Ubiquitously expressed rat cyclophilin<sup>18</sup> was used as a control for equal loading of lanes. RNA size standards are indicated to the right in kb. **b**, The IG3.B9A mRNA has aberrant size and abundance in *rds/rds* retina. rd, 6–7-week-old C3H/HeJ retina; B/c, 4–8-week-old BALB/c retina; *rds*, 4–8-week-old *rds/rds* (O20/cpb) retina. **c**, same northern blot as **b** re-probed with cDNA clone 2H2 of the mouse opsin mRNA.

**METHODS.** Total cellular RNA was prepared from the indicated mouse retinas and brain<sup>19</sup>. Enrichment for poly(A)<sup>+</sup> RNA was performed on oligo(dT) cellulose<sup>20</sup>. Northern blots were prepared by electrophoresis in 1% agarose formaldehyde gels and transferring to nitrocellulose<sup>21</sup>. Each lane contained 2 µg of poly(A)<sup>+</sup> RNA. cDNA libraries were prepared from C57BL/6 and C3H/HeJ retina poly(A)<sup>+</sup> selected RNA in the plasmid vector pGEM4<sup>13</sup>. Plasmid DNA from the amplified C3H/HeJ library was used as a hybridization driver to subtract common sequences from a C57BL/6 <sup>32</sup>P-labelled cDNA probe as previously described<sup>13</sup>. The subtracted probe was used to screen the C57BL/6 library. Positive clones were checked for hybridization with unsubtracted C57BL/6 but not C3H/HeJ cDNA in a differential colony screen. Insert DNA from individual clones selected by the above screen was labelled with [<sup>32</sup>P]dCTP as described<sup>22</sup> and was used to probe northern blots. Final stringency wash conditions were 0.2 × SSC/0.2% SDS at 68 °C.

(Table 1). A full-length cDNA clone (IG3.B9A), containing an insert of approximately 2.7 kilobase (kb), was isolated by re-probing the C57BL/6 retinal cDNA library with clone IG3.

Clone IG3.B9A was used to probe northern blots containing RNA from the retinas of 1–2-month-old (pre-degenerate) *rds/rds* mice (BALB/c background) and age-matched wild-type (BALB/c) mice (Fig. 1b). Two major mRNA species of approximately 1.6 kb and 2.7 kb (estimated abundance, 0.05%) were observed in the BALB/c retina lane. These bands were not present in the *rds/rds* retina lane. A faint doublet band of approximately 12 kb was detected in the *rds/rds* lane however, which was not present in the BALB/c lane. Thus, the mRNAs detected with clone IG3.B9A in the retinas of *rds* mice are aberrant in size and abundance, suggesting that IG3.B9A is a clone of the wild-type *rds* mRNA.

When the same northern blot was re-probed with a cDNA clone of the opsin mRNA (clone 1-2H2 in Fig. 1a), the BALB/c and *rds/rds* retina lanes exhibited identical hybridization patterns, although the signal intensity in the mutant lane was slightly reduced (Fig. 1c), consistent with partial degeneration of photoreceptors. This experiment excluded the possibility that the observed difference in RNA hybridization patterns with the

IG3.B9A probe in wild-type and *rds/rds* retina was due to premature degeneration of photoreceptors in the mutant, or to a generalized abnormality in RNA processing within photoreceptors in *rds/rds*.

To define the site of the mutation within the putative *rds* locus, five adjacent non-overlapping restriction endonuclease fragments spanning the full-length cDNA clone IG3.B9A were prepared (Fig. 2a). These fragments were used individually as probes to examine restriction digests of genomic DNA prepared from BALB/c and *rds/rds* mice on Southern blots. Restriction fragment length polymorphisms (RFLPs) were detected in the DNA of BALB/c relative to *rds/rds* mice with probe B9A-II (Fig. 2b), but not with probes B9A-I, -III, -IV or -V (data not shown).

Genomic libraries prepared with the DNA from BALB/c and *rds/rds* mice were probed with cDNA clone IG3.B9A. A clone B7 was isolated from the BALB/c library and a clone R24 was isolated from the *rds/rds* library. The λ-cloned DNAs gave similar hybridization patterns to their corresponding wild-type or mutant genomic DNAs on Southern blots probed with cDNA clone fragment B9A-II (Fig. 2b).

To define the mutation at the nucleotide level, the 2.8 kb *Pst*I

FIG. 2 **a**, Restriction map of the *rds* cDNA clone IG3.B9A derived from the nucleotide sequence (see Fig. 3). The open reading frame is indicated by the open box. Restriction fragments (B9A-I-V) used as probes for Southern blot analysis are indicated below. **b**, Southern blot analysis of genomic and  $\lambda$  clone DNA with IG3.B9A fragment II probe. B/c, BALB/c DNA; *rds*, *rds/rds* DNA (10  $\mu$ g genomic DNA per lane); B7,  $\lambda$  clone B7 from BALB/c library; R24,  $\lambda$  clone R24 from *rds/rds* library (0.5 ng  $\lambda$  clone DNA plus 10  $\mu$ g sheared salmon sperm DNA per lane). DNA samples were digested with restriction endonuclease *Bgl*II, *Pst*I, or *Bgl*II plus *Pst*I as indicated. DNA size standards are indicated to the right in kb. Electrophoresis, transfer to nitrocellulose, preparation of probes and stringency wash conditions as described in Table 1.

**c**, Restriction map of BALB/c and *rds/rds* genomic clones. B:1 is the 2.8 kb *Pst*I genomic subclone fragment from wild-type phage  $\lambda$  clone B7 detected with probe B9A-II. R:1 is the 6.3 kb *Pst*I genomic subclone fragment from *rds/rds* phage  $\lambda$  clone R24 detected with probe B9A-II. The open box indicates an exon which contains a protein-coding region (see Fig. 3). The wavy line indicates the insertion in the mutant locus. The nucleotide sequences of B:1 and R:1 in the region containing the divergence is indicated below. Capital letters in the nucleotide sequence correspond to the wild-type exon; lower-case letters correspond to the insertion. Bars underneath the restriction map show the origin of the indicated sequences.

Southern blots containing DNA from mouse  $\times$  hamster somatic cell hybrids were probed with cDNA clone IG3. Column designations: +/+, chromosome and IG3 hybridization signal both present; -/-, chromosome and hybridization signal both absent; +/-, chromosome present and hybridization signal absent; -/+, chromosome absent and hybridization signal present. A hybridization signal corresponding to the hamster allele was present in all cell lines. 10  $\mu$ g DNA samples from 16 mouse  $\times$  hamster hybrid cell lines containing different mouse chromosomes<sup>14</sup> were digested with restriction endonuclease *Pst*I and resolved by electrophoresis on 0.7% agarose. The DNA was transferred to nitrocellulose<sup>17</sup> and then probed with DNA from clone IG3 (see Fig. 1). Final stringency wash conditions were 0.2  $\times$  SSC/0.2% SDS at 68  $^{\circ}$ C.

fragment from (wild-type)  $\lambda$  clone B7 and the 6.3 kb *Pst*I fragment from (*rds/rds*)  $\lambda$  clone R24 detected by B9A-II were both subcloned. Restriction endonuclease mapping of these subcloned *Pst*I fragments (B:1 and R:1) revealed that the 5' 2.7 kb of each were indistinguishable. After the third *Ava*I site (Fig. 2c), the restriction maps of B:1 and R:1 diverged. The 0.25 kb *Ava*I-*Pst*I 3' fragment from the wild-type subclone B:1, and the corresponding 0.95 kb *Ava*I-*Ava*I fragment from the mutant subclone R:1 were isolated and their nucleotide sequences determined. The sequences were identical up to the position corresponding to nucleotide 899 in the mRNA (see below a' Fig. 3). At this point, a foreign sequence appears in the mutant gene, disrupting the protein-coding exon (Fig. 2c). As the mutation occurs within an exon, this foreign sequence is probably transcribed in *rds/rds*. The observed increase in the size of the transcripts detected with clone IG3.B9A in the retinas of *rds/rds* mice is consistent with the insertion of approximately 10 kb of foreign DNA into an exon of the *rds* gene.

In an attempt to identify this foreign insert, we used Southern blots to analyse genomic DNA isolated from BALB/c and *rds/rds* using the 0.4 kb *Sac*I-*Ava*I restriction fragment from the inserted element of R:1 (Fig. 2c) as a probe. About 30 bands were detected in both the wild-type and *rds/rds* lanes, with two additional bands present in the *rds/rds* lanes that were absent from the wild-type lanes (data not shown). A computer database search was performed with the nucleotide sequence from the 0.4 kb *Sac*I-*Ava*I fragment of R:1 (data not shown). No significant similarity to any eukaryotic or viral sequences was detected. Based upon its size (approximately 10 kb) and its copy number in the mouse genome (10-30 copies), this inserted DNA may represent an unidentified retrovirus-like element.

Sequence analysis of the IG3.B9A cDNA revealed an insert containing 2,632 base pairs (bp) followed by a poly(A) tail (Fig. 3). A single long open reading frame began at nucleotide 213, encoding a putative protein of 346 amino acids. A common

**FIG. 3** Nucleotide sequence of the full-length *rds* cDNA clone IG3.B9A. Nucleotide numbering is shown on the left. The single long open reading frame has the corresponding amino-acid sequence translated above. The polyadenylation signal CATAAA for the 1.6 kb mRNA (IG3.D6), and ATTTAA for the 2.7 kb mRNA (IG3.B9A) are underlined. **METHODS.** The sequence was determined by a modified version<sup>23</sup> of the chemical degradation method of Maxam and Gilbert<sup>24</sup>. The complete sequence was determined for both DNA strands of clones IG3.B9A and IG3.D6 (see below). Primer extension analysis was performed on clone IG3.B9A as described<sup>25</sup> using a synthetic deoxyoligonucleotide corresponding to the antisense strand of IG3.B9A from position 64 to 41 (data not shown). cDNA clone D6 of the small, wild-type *rds* transcript was isolated by screening for clones that hybridized with full-length clone IG3.B9A but failed to hybridize to a truncated clone containing 0.6 kb from the 3' end of IG3. The sequence of clone IG3.D6 was identical to IG3.B9A except for the use of an alternative polyadenylation signal.

variant (AUUAAA)<sup>15</sup> of the consensus polyadenylation signal (AAUAAA)<sup>16</sup> was found 20 nucleotides upstream from the poly(A) tail. Primer extension analysis showed that IG3.B9A was only six nucleotides short of being a full-length clone of the 2.7 kb mRNA (see Fig. 3 legend). A cDNA clone of the 1.6 kb *rds* transcript (IG3.D6) was isolated by further screening (Fig. 3 legend). Sequence analysis of IG3.D6 showed that the 1.6 kb mRNA was identical to the 2.7 kb mRNA except that the poly(A) tail began 24 bases downstream from the alternative polyadenylation signal CAUAAA<sup>15</sup>, at position 1,651 rather than 2,633.

A computer search of a protein sequence database (Protein Identification Resource, 31 March 1988) with the predicted protein encoded by the *rd5* mRNA revealed no significant similarities to any known protein sequences. The *rd5* protein (relative molecular mass,  $M_r$  39,259) does not seem to have an N-terminal secretion signal sequence. It does contain three uncharged regions (amino acids 16-41, 100-122 and 252-275) which may represent membrane-spanning domains. Four sets of tandem basic residues (amino-acid residues: 11-13, 46-48, 178-179 and 324-325) are possible candidates for proteolytic cleavage signals. The protein also contains 13 cysteine residues which are potential sites for intra- or inter-chain disulphide linkages. As the *rd5* mRNA has been shown here to be photoreceptor-specific within the retina and is not detectable in brain, it is possible that the *rd5* protein function relates to some photoreceptor-specific process, possibly as an unidentified member of the visual transduction cascade. As the insertion occurred within a protein-coding exon, the resulting protein will be aberrant, lacking its normal C-terminal 87 amino-acid residues if translation of the aberrant *rd5* mRNA does occur in *rd5/rd5* retina.

From the evidence presented here, we concluded that we have cloned the *rds* gene and characterized its normal mRNA products. This is the first molecular description of a gene determining neuronal degeneration in a mammalian system where nothing was known in advance about the gene product. It remains a

formal possibility that the gene identified here is not *rdx*: if loss of function of the identified gene product is not lethal to photoreceptors and if another gene on chromosome 17 which is also expressed in photoreceptors bears an independent second mutation. Final proof that the identified gene is indeed *rdx* will await correction of the phenotype by introducing DNA from the cloned wild-type allele into the *rdx/rdx* background in a transgenic experiment. Elucidation of the mechanism of photoreceptor degeneration in *rdx/rdx* will need studies of the *rdx* gene product. The first steps towards this involve immunocytochemical localization of the *rdx* protein within photoreceptors, and the identification of other proteins which may be physically associated. □

# Does T-cell tolerance require a dedicated antigen-presenting cell?

Polly Matzinger & Sylvie Guerder

Basel Institute for Immunology, Grenzacherstrasse 487,  
CH-4005 Basel, Switzerland

ALMOST 30 years ago Burnet proposed that the immune system maintained self-tolerance by deleting autoreactive lymphocytes<sup>1</sup>. Recently it has become clear that for T cells this step occurs in the thymus, where developing T cells first express their antigen-specific receptors<sup>2-4</sup>. Here a T-cell which encounters its antigen disappears—if it is not dead, it at least stops expressing its receptors. In the periphery by contrast, encounter with antigen leads to activation and proliferation of the responding T-cell. There are two possible explanations for this difference. Either the antigen-presenting cells in the thymus are different from those in the periphery and instead of producing positive signals they directly or indirectly kill the thymocytes<sup>5,6</sup>; or the T cells themselves are different, and like immature B cells, may die after encounter with antigen<sup>7,8</sup>. We tested the first possibility and found that dendritic cells from spleen, which are the most potent activators of mature T cells<sup>9</sup>, are also the most potent inactivators of young developing T cells. Thus it is not the antigen-presenting cell which determines whether a T-cell responds or dies, but the T-cell itself or its thymic environment.

To analyse the activity of various cell types, we used *in vitro* thymus organ cultures<sup>10,11</sup>. We cultured embryonic mouse thymus lobes from 14-day-old fetal B6 or (B6 × BALB/c) mice for 7 days. At day 14 of gestation these thymuses have no mature T cells<sup>12,13</sup>, but by day 21 the T cells have matured<sup>11</sup> and can be activated by mitogens<sup>11</sup> or in mixed-lymphocyte reactions<sup>14</sup>.

Figure 1 shows the result of two experiments designed to find out whether it was possible to tolerize cytotoxic T cells developing *in vitro*. Since it had been shown that proliferating T cells can be rendered specifically unresponsive if they are co-cultured with allogeneic adult<sup>11</sup> or fetal<sup>15</sup> thymus cells, we cultured the fetal thymuses in contact with a slice of irradiated adult allogeneic (SJL or CBA) thymus. Figure 1a and c shows that fetal T cells can develop into cytotoxic T lymphocytes (CTL) specific for allogeneic C3H.Q, CBA or SJL stimulators. Fig. 1b and d demonstrates that co-culture with adult thymic tissue generates specific unresponsiveness. Thymuses co-cultured with CBA (Fig. 1b) no longer generated CTL against CBA, but remained totally responsive to C3H.Q, whereas thymuses co-cultured with SJL became tolerant of SJL while maintaining their activity against CBA (Fig. 1d). Using limiting-dilution analysis (not shown), we found that the frequency of cells responding to the co-cultured thymus was decreased 100- to 1000-fold. Thus it was clear that the *in vitro* development of immature T cells is sufficiently similar to their *in vivo* development to allow both maturation and tolerance of specific CTL.

Although it has been assumed for some time that the 'tolerizing' antigen-presenting cell (APC) in the thymus is a bone marrow-derived dendritic cell<sup>15</sup>, a VETO cell<sup>5</sup> or a double-

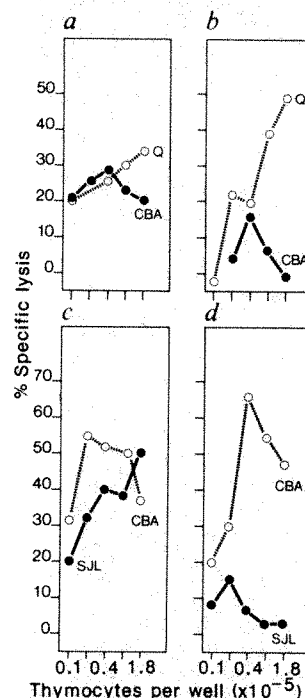

FIG. 1 Tolerance *in vitro*. Details of the mouse strains are shown in Table 1. We removed thymuses from 14-day (B6 × BALB/c) mouse fetuses and cultured them on millipore filters at the liquid-air interface in Iscove's modified Dulbecco's medium with 10% fetal calf serum, antibiotics and  $6 \times 10^{-5}$  M  $\alpha$ -thioglycerol<sup>11</sup>. The thymuses were either cultured alone (a, c; 8–10 per filter) or around and in contact with a slice (~1 mm thick) of irradiated (1,000 rads) adult CBA (b) or SJL (d) thymus. Activation cultures and cytotoxic assay: After 7 days thymocytes were collected and graded (indicated as numbers of thymocytes per well) into round-bottomed 96-well microtitre plates with  $5 \times 10^5$  irradiated (3,000 rad) adult spleen stimulator cells in medium including 10% supernatant from concanavalin-A activated rat spleen cells plus 20 mM  $\alpha$ -methylmannoside. After 6 days the medium was removed and replaced with 0.2 ml medium containing  $10^4$   $^{51}\text{Cr}$ -labelled targets (spleen cells cultured for 2 d with  $2 \mu\text{g ml}^{-1}$  concanavalin A). Released  $^{51}\text{Cr}$  was collected after 3.5 h. Cytotoxicity (per cent) was averaged from triplicate cultures and calculated from: (experimental release – spontaneous release)/(maximum release – spontaneous release)  $\times 100$ . Lytic activity is shown against the stimulating cell type. The activity on inappropriate targets was never >20% of the specific activity and was usually <1%. Occasionally (~1/8 experiments) the level of nonspecific cytotoxicity is anomalously high and so these experiments are excluded. The somewhat unusual shape of the cytotoxicity curves probably results from two factors: at low cell numbers we are at limiting dilution conditions and single active clones can sporadically appear to generate unusual peaks of activity; also, in a very active response, high cell numbers will deplete the culture medium and die before the assay. We would therefore see efficient CTL activity only at lower inputs. a, c, Thymuses cultured alone; b, co-cultured with CBA; d, co-cultured with SJL.

negative thymocyte<sup>16</sup>, it is not known whether the tolerizing cell must come from the thymus or whether the newly developing T-cell can be rendered unresponsive after interaction with any APC. To distinguish between the two alternatives, we tested the tolerizing capacity of dendritic cells from adult spleen. In the activation of mature T cells, splenic dendritic cells are among the most efficient of APCs<sup>9</sup>. Would they activate or tolerize newly developing thymocytes?

Figure 2a shows the responses of (B6 × BALB/c) thymocytes which have developed alone or in the presence of graded numbers of irradiated dendritic cells from the spleens of adult CBA mice. Thymocytes that developed alone generated good CTL against both CBA and C3H.Q, whereas thymocytes that developed in the presence of even small numbers of CBA dendritic cells responded to C3H.Q but were no longer respon-

FIG. 2 Dendritic cells induce tolerance *in vitro* and *in vivo*. *a*, Thymic organ culture *in vitro*. Each 14-day fetal thymus lobe was cultured in a 20  $\mu$ l Terasaki well (upside down) in the presence or absence of graded numbers of irradiated (1,000 rads) CBA dendritic cells (20 thymus lobes per group). After 18 h each lobe was rinsed, transferred to a Millipore filter, and cultured for another 6 d. For the activation culture the 20 lobes in each group were pooled, activated and tested as described in Fig. 1 legend. The number of dendritic cells per lobe is given above each panel. *b*, Thymic organ culture *in vivo*. Thymuses were cultured overnight with CBA dendritic cells. They were then rinsed and grafted under the left kidney capsule of adult SCID mice

(8–10 lobes per mouse, 2 mice per group). After 11 days the thymocytes were collected, pooled, activated and tested. Isolation of dendritic cells: 1–2  $\times 10^8$  spleen cells per dish were cultured in 5 ml Petri dishes for 2 h, stringently washed free of all non-adherent cells. The remaining cells were then re-cultured for 18 h and the non-adherent cells gently collected. The yield varied from 0.1–0.3% of input, contained no cells positive for Thyl or immunoglobulin and <0.01% Fc receptor-positive cells. In our hands these dendritic cells were 20–30 fold more effective than spleen cells at presenting antigen to T-cell clones.

sive to CBA. Figure 2b shows that dendritic cells have the same effect *in vivo*. We added graded numbers of CBA dendritic cells, cultured the thymuses overnight and then allowed them to develop for 11 days under the kidney capsules of SCID mice (which cannot generate their own T or B cells<sup>17</sup>). Again, the presence of adult spleen dendritic cells specifically abolished responsiveness.

The number of dendritic cells which induce unresponsiveness is small and is correlated with the size of the thymus. *In vitro* the thymuses develop 2–5  $\times 10^5$  thymocytes per lobe, whereas *in vivo* the same thymuses will enlarge to 1–4  $\times 10^6$ . This 10-fold difference is reflected in the number of allogeneic dendritic cells needed for tolerance. On the average, complete tolerance is achieved with one dendritic cell per 200 thymocytes *in vitro* and *in vivo*. In tissue sections (not shown) we found that, like dendritic cells in normal thymus<sup>18</sup>, our dendritic cells do not distribute randomly throughout the thymus, but seem to collect into tubules or clusters in the medulla and at the cortico-medullary junction. Perhaps young T cells must run a gauntlet of dendritic cells before they are allowed to leave the thymus.

Figure 3 indicates that other cell types are not as effective as dendritic cells. It takes 1–2  $\times 10^3$  dendritic cells to remove 90% of the thymocyte responsiveness against them, but 100-fold more spleen cells and 1,000-fold more thymocytes are required to achieve the same effect. This difference correlates well with the frequency of dendritic cells in each population<sup>9</sup>, implying that antigen presentation for tolerance, like antigen presentation for activation, is best done by a typical APC, and that dendritic cells, the most effective activators of mature T cells, are also the most effective inactivators of young thymocytes.

The tolerizing ability of dendritic cells could solve two long standing problems. The first involves tolerance to peripheral tissue-specific antigens which are not expressed by the thymus<sup>19,20</sup>. It cannot be argued that the thymus specializes in the expression of each possible self-antigen, because tetraparental embryo-fusion chimaeras express antigens on their syncytiated muscle cells that cannot be expressed elsewhere (including in the thymus)<sup>19</sup>, and yet these mice are tolerant of their muscle. Since peripheral APCs circulate through the thymus<sup>21</sup>, they could well pick up a variety of antigens on the way, which they could then present to the developing thymocytes, thereby generating at least some level of tolerance to peripheral antigens.

Of course this does not exclude the existence of peripheral suppressive 'fail-safe' mechanisms to ensure self-tolerance should thymic depletion be imperfect<sup>32</sup>. The second problem concerns extrathymic differentiation<sup>22</sup>. Nude mice, for example, have no thymuses, yet small numbers of T cells can be found. These T cells can be activated against allogeneic and haptenated targets<sup>23</sup> but they are totally tolerant of self. If the decision to respond or be turned off is actually made by the developing T-cell rather than by the APC, then any T cells developing outside the thymus will also be rendered self-tolerant. Thus the system provides a safety valve that allows for extrathymic differentiation of T cells (and for potential evolutionary side-steps).

Tolerance induction by normal peripheral APCs also allows for conservation of specificity. We know that tolerance, like

FIG. 3 Comparison of the effect of different cell populations. 14-day (B6  $\times$  BALB/c) thymuses were cultured with graded numbers of irradiated adult CBA spleen or thymus cells or purified dendritic cells as described in Fig. 1 legend. The ordinate represents the highest level of cytotoxicity seen in the titrated culture of each (pooled) group of thymocytes; the abscissa represents the number of 'tolerizing' cells per lobe. For comparison, the first panel is the same experiment as that shown in Fig. 2a. The highest point in each panel of Fig. 2a becomes one point on the curve here.

activation, is MHC-restricted<sup>24,25</sup>, and that antigen-processing is probably involved<sup>26,27</sup>. According to Bretscher and Cohn<sup>28</sup> 'every inducible cell must be tolerizable' and it should be tolerizable by the same antigen, at the same concentration and presented in the same way as the one to which it could be activated. If T cells are normally activated by peripheral APCs then it makes sense to tolerize them using the same APCs.

Here we have established that tolerance is not uniquely the result of antigen presentation by a special set of thymic antigen-presenting cells. Young thymocytes can be turned off when they recognize antigen on the same types of APCs that activate mature T cells. It could be argued that the peripheral dendritic cell might change its role on entering the thymus, turning from an activator into a tolerizer. Two sets of results stand against this. First, APCs isolated from the thymus can stimulate T-cell clones<sup>29</sup>. Second, mature T cells in the thymus can be primed by a peripheral injection of spleen cells<sup>30</sup>. We favour the view that the decision for tolerance, as opposed to activation, is made by the T cells themselves at different stages of their development. Whether the young thymocytes are innately suicidal or in need of critical, but unavailable, growth factors<sup>31</sup> remains to be investigated. □

## Positive selection of CD4<sup>+</sup>CD8<sup>+</sup> T cells in the thymus of normal mice

Juan Carlos Zúñiga-Pflucker, Dan L. Longo & Ada M. Kruisbeek\*

Biological Response Modifiers Program, National Cancer Institute, Building 10, Room 12N226, National Institutes of Health, Bethesda, Maryland 20892, USA

THE diversification of the repertoire of T-cell antigen receptor (TCR) specificities is influenced by at least two selection processes which occur in the thymus<sup>1–6</sup>. One of these, termed 'negative selection', is required to install a state of tolerance to self-antigens in the T-cell repertoire and is often achieved by clonal deletion<sup>7–11</sup>. The second type of selection operating in the thymus results in preferential differentiation of T cells that have restriction specificity for thymic major histocompatibility complex glycoproteins, but the mechanisms leading to this selective process are not yet clear. One model used to describe this 'positive selection' proposes that only those T cells with sufficient avidity for the MHC glycoproteins expressed in the thymus are allowed to acquire functional competence<sup>1–4,12,13</sup>. Here we directly investigate the generation of TCR specificities by following the fate of developing Vβ17<sup>+</sup> CD4<sup>+</sup>CD8<sup>+</sup> T cells under conditions where one of the main class I-MHC molecules, either H-2K or H-2D, was specifically blocked by *in vitro* monoclonal antibody treatment<sup>14</sup>. The results show that development of Vβ17<sup>+</sup> CD4<sup>+</sup>CD8<sup>+</sup> T cells in the SJL H-2<sup>s</sup> mouse strain is selectively abrogated by blocking class I-K<sup>s</sup> molecules but is unaffected by blocking class I-D<sup>s</sup> molecules. These data directly demonstrate that generation of CD4<sup>+</sup>CD8<sup>+</sup> T cells expressing a particular TCR Vβ segment can be correlated with the expression of a particular class I-MHC molecule, thereby providing evidence for positive selection.

The TCR-Vβ17a product confers reactivity to various allelic forms of the murine class II-MHC molecule I-E (refs 7 and 15)

and is differentially expressed among the CD4<sup>+</sup>CD8<sup>+</sup> and CD4<sup>+</sup>CD8<sup>+</sup> T-cell subsets of different mouse strains. For instance, SWR (H-2<sup>q</sup>) mice express Vβ17a predominantly in CD4<sup>+</sup>CD8<sup>+</sup> T cells, whereas SJL (H-2<sup>s</sup>) mice express Vβ17a in both CD4<sup>+</sup>CD8<sup>+</sup> and CD4<sup>+</sup>CD8<sup>+</sup> T cells<sup>7,16</sup>. One possible explanation for this is that the class I-MHC glycoproteins of the H-2<sup>s</sup> haplotype, but not those of the H-2<sup>q</sup> haplotype, allow for positive selection of the Vβ17<sup>+</sup> CD4<sup>+</sup>CD8<sup>+</sup> T cells. An inference from this hypothesis is that blocking one of the H-2<sup>s</sup>-class I MHC molecules could prevent the generation of Vβ17<sup>+</sup> CD4<sup>+</sup>CD8<sup>+</sup> T cells in H-2<sup>s</sup> mice without affecting the overall development of CD4<sup>+</sup>CD8<sup>+</sup> T cells.

To test this prediction, we treated SJL (H-2<sup>s</sup>) mice from the day of birth with anti-class I monoclonal antibody (mAb) against either K<sup>s</sup> (mAb 34-1-2; ref. 17; mouse γ2a) or D<sup>s</sup> (mAb 15-1-5; ref. 18; mouse γ2b). The doses used (500 µg per gram body weight administered daily until analysis at 2–3 weeks of age)<sup>14</sup> were sufficient to saturate the appropriate class I-MHC on spleen

TABLE 1 Expression of Vβ17 by thymocytes from control, anti-K<sup>s</sup>-treated, and anti-D<sup>s</sup> treated H-2<sup>s</sup> mice

Treatment	Vβ17a in CD3 <sup>+</sup> CD4 <sup>+</sup> CD8 <sup>+</sup> cells	Vβ17a in CD3 <sup>+</sup> CD4 <sup>+</sup> CD8 <sup>+</sup> cells
Experiment 1		
Control	5.7	23.5
Anti-K <sup>s</sup>	0.3	23.9
Anti-D <sup>s</sup>	5.9	22.6
Experiment 2		
Control	5.4	20.9
Anti-K <sup>s</sup>	0.1	22.3
Anti-D <sup>s</sup>	4.8	22.4
Experiment 3		
Control	4.8	19.2
Anti-K <sup>s</sup>	0.1	23.2
Anti-D <sup>s</sup>	4.6	20.6

Mice were treated with anti-K<sup>s</sup> or anti-D<sup>s</sup> mAb as for Fig. 1. Thymocytes were enriched for receptor-bearing single positive cells by treatment with M1/69 plus complement as described in Fig. 2. Data are presented as percent positive cells (values for control-staining subtracted).

**FIG. 1** Flow cytometry analysis of cell-surface class I-H-2D<sup>s</sup> and class I-H-2K<sup>s</sup> expression on thymocytes from control and anti-K<sup>s</sup>-treated mice. Cells were stained with anti-D<sup>s</sup>-mAb (a, solid lines) or anti-K<sup>s</sup>-mAb (b, solid lines). Staining with irrelevant control mAb (dashed lines) is shown for only one of the cell samples (control or anti-K<sup>s</sup>-treated). **METHODS.** Neonatal SJL (H-2<sup>s</sup>) mice were treated within 24 h of birth with anti-K<sup>s</sup> mAb (hybridoma 34-1-2, ref. 17; reactive with K<sup>s</sup>D<sup>s</sup> and cross-reactive with K<sup>s</sup>) or anti-H-2D<sup>s</sup> mAb (hybridoma 15-1-5, ref. 18; reactive with K<sup>s</sup>D<sup>s</sup> and cross-reactive with D<sup>s</sup>). Hybridomas were obtained from ATCC (American Type Culture Collection) and purified from ascites by ammonium sulphate precipitation followed by size separation. Mice were injected daily with 500 µg mAb per gram body weight and their thymocytes analysed at 2–3 weeks of age in 4 separate experiments. Thymocytes were pretreated *in vitro* with mAb M1/69 (ref. 20) plus complement to enrich for mature T cells (see Fig. 2), and stained with either fluorescein isothiocyanate-labelled 15-1-5 (anti-D<sup>s</sup>) mAb (a) or biotinylated 34-1-2 (anti-K<sup>s</sup>) mAb, followed by allophycocyanin-labelled avidin (Caltag, San Francisco) (b). Flow cytometry analysis was performed on a B-D Dual Laser 440 interfaced to a PDP 11/24 computer<sup>14</sup>. Data were collected on 50,000 viable cells and are shown for control and anti-K<sup>s</sup>-treated mice. Reciprocal results are obtained in anti-D<sup>s</sup> treated mice, in that D<sup>s</sup>-staining is reduced and K<sup>s</sup>-staining is normal (data not shown). Staining with appropriate anti-mouse IgG antibody revealed that reduced staining was due to blocking by mAb (not shown). Control mice were treated with saline, once preliminary experiments had shown<sup>14</sup> that daily injection with equally high amounts of non-binding anti-class I mAb had no effect.

cells (data not shown) and thymocytes (Fig. 1). Flow cytometry analysis of anti-K<sup>s</sup>-treated mice revealed there had been a strong blocking of K<sup>s</sup> while D<sup>s</sup>-expression was left undisturbed. Reciprocal results, with D<sup>s</sup>-blocking and normal K<sup>s</sup> expression, were observed in anti-D<sup>s</sup>-treated mice (data not shown).

We next investigated Vβ17a expression in developing thymocytes from H-2<sup>s</sup> mice treated from birth with anti-K<sup>s</sup> or anti-D<sup>s</sup>. Although treatment of newborn homozygous mice with anti-class I mAb specific for both H-2K<sup>s</sup> and H-2D<sup>s</sup>-encoded glycoproteins prevents generation of most CD4<sup>+</sup>CD8<sup>+</sup> T cells<sup>14</sup>, treatment of newborn F<sub>1</sub> mice with anti-class I mAbs that are specific for only one of the two parental haplotypes has no effect on the total number of CD4<sup>+</sup>CD8<sup>+</sup> T cells<sup>14</sup>. By analogy, treatment of homozygous mice with anti-class I mAb specific only for either H-2K<sup>s</sup> or H-2D<sup>s</sup>-region-encoded products has no effect on overall development of mature CD3<sup>+</sup>CD4<sup>+</sup>CD8<sup>+</sup> T cells<sup>19</sup> (see also Fig. 2). Thus, selective anti-K<sup>s</sup> or anti-D<sup>s</sup> mAb treatment of H-2<sup>s</sup> mice will allow for TCR-repertoire analysis of developing CD4<sup>+</sup>CD8<sup>+</sup> T cells. To enrich for TCR-bearing cells, thymocytes from control or treated mice were subjected to M1/69 (ref. 20) plus complement *in vitro* before analysis of TCR expression. The M1/69 mAb recognizes an epitope on the same molecule as the JIId mAb (ref. 21) and eliminates almost all CD4<sup>+</sup>CD8<sup>+</sup> thymocytes (see also Fig. 2) and a subset of CD4<sup>+</sup>CD8<sup>+</sup> thymocytes<sup>22</sup>. Anti-D<sup>s</sup>-mAb treatment has no effect

**FIG. 2** Two-colour flow cytometry analysis of cell-surface CD8 expression versus Vβ17a-TCR (top) or CD3 (bottom) on thymocytes from SJL (H-2<sup>s</sup>) mice which were untreated (left), treated from birth with anti-K<sup>s</sup> mAb (middle), or treated from birth with anti-D<sup>s</sup> mAb (right). Cells were stained first with FITC-conjugated anti-Vβ17 mAb or FITC-conjugated anti-CD3 mAb, then washed and stained with biotinylated anti-CD8 mAb followed by allophycocyanin-labelled avidin.

**METHODS.** Mice were treated with anti-K<sup>s</sup> or anti-D<sup>s</sup> mAbs until they were 3 weeks old, as described in Fig. 1. Thymocytes were treated with mAb M1/69 (ref. 20) plus complement to enrich for mature T cells, and stained for Vβ17a-expression with FITC-conjugated KJ23 (ref. 15) or for CD3-expression with FITC-conjugated 145-2C11 (ref. 32). Cells were then washed and stained for CD8 with biotinylated 53.6 mAb. Data were collected as described in Fig. 1 and displayed as contour diagrams. Per cent Vβ17a-expressing cells: for CD3<sup>+</sup>CD4<sup>+</sup>CD8<sup>+</sup> cells, 5.7% in control; <0.5% in anti-K<sup>s</sup>-treated; 5.9% in anti-D<sup>s</sup>-treated. Per cent Vβ17a-expressing cells in CD3<sup>+</sup>CD4<sup>+</sup>CD8<sup>+</sup> cells: 23.5% in control; 23.9% in anti-K<sup>s</sup>-treated; 22.6% in anti-D<sup>s</sup>-treated; these last values were derived from Vβ17a versus CD4 staining (not shown).

on Vβ17a-expression in either one of the subsets of mature T cells (Fig. 2, top). In striking contrast, thymocytes from anti-K<sup>s</sup> treated mice exhibited virtually no Vβ17a-expression in the CD4<sup>+</sup>CD8<sup>+</sup> subset (Fig. 2, top) (<0.5% in treated versus 5.7% in control); a summary of three experiments is shown in Table 1. The effect of the anti-K<sup>s</sup> treatment on Vβ17a-TCR bearing CD4<sup>+</sup>CD8<sup>+</sup> cells was specific in that it did not affect the total number of CD3<sup>+</sup>CD4<sup>+</sup>CD8<sup>+</sup> T cells (Fig. 2, bottom), nor did it have any effect on the generation of Vβ17a<sup>+</sup>CD4<sup>+</sup>CD8<sup>+</sup> cells (Fig. 2, top; 23.9% in treated versus 23.5% in control). This highly selective perturbation of the TCR-repertoire of CD4<sup>+</sup>CD8<sup>+</sup> T cells is strong evidence that development of CD4<sup>+</sup>CD8<sup>+</sup> T cells with a certain TCR requires expression of particular alleles of the class I-MHC glycoproteins. These findings indicate that TCR-MHC ligand interactions provide signals essential to the differentiation of precursor T cells, and are evidence in favour of the positive-selection theory.

Our results on T-cell repertoire development in anti-class I-treated normal mice confirm the proposed thymic selection inferred indirectly from chimera models<sup>1–4</sup>. The data are also consistent with the observation that anti-class II-treated F<sub>1</sub> mice, in which the mAb can react with only one of the parental haplotypes, express a significantly altered repertoire<sup>23</sup>, with T-helper cells showing self-class II restriction for the unblocked class II-molecules only. In a third model system using αβ-TCR-transgenic mice<sup>10,24–26</sup>, positive selection in the context of thymic MHC also occurs, a result which together with ours shows the importance of TCR-MHC interactions in the development of T cells. Our data also bear on another aspect of TCR-repertoire selection, namely the degree to which certain TCR V gene elements can independently account for preferential recognition

of particular alleles of MHC glycoproteins. Several of the murine V $\beta$  genes so far examined have, when expressed on CD4<sup>+</sup>CD8<sup>+</sup> T cells, been associated with recognition of particular class II MHC molecules and self-antigens<sup>7-9,27-29</sup>. The observation that V $\beta$ 17a-bearing CD4<sup>+</sup>CD8<sup>+</sup> T cells are not generated in anti-K<sup>s</sup>-treated H-2<sup>s</sup> mice leads to the prediction that V $\beta$ 17a alone might confer restriction specificity for K<sup>s</sup>, regardless of the V $\alpha$  sequences expressed on its partner chain and of junctional sequences. Thus, all V $\beta$ 17a<sup>+</sup> CD4<sup>+</sup>CD8<sup>+</sup> T cells are expected to be K<sup>s</sup>-restricted. Although this prediction can be tested by analysing the restriction specificities of various antigen-specific V $\beta$ 17a-bearing CD4<sup>+</sup>CD8<sup>+</sup> T cells derived from H-2<sup>s</sup> mice, we have not yet been able to generate such cells, presumably because the vast number of potential foreign antigens precludes an easy definition of the appropriate ones. Nonetheless, the most straightforward explanation of our results is that V $\beta$ 17a<sup>+</sup> CD4<sup>+</sup>CD8<sup>+</sup> T cells are preferentially selected on K<sup>s</sup>, or by K<sup>s</sup> complexed to self-peptides<sup>30,31</sup>. Another explanation arises if we consider the opposite possibility that expression of certain TCR V gene elements precludes recognition of particular MHC molecules. According to such a model, all V $\beta$ 17a CD4<sup>+</sup>CD8<sup>+</sup> are apparently selected on K<sup>s</sup> not because V $\beta$ 17a 'dictates' K<sup>s</sup> recognition, but because a TCR with V $\beta$ 17a cannot interact with D<sup>s</sup>; complexing of D<sup>s</sup> with those self-peptides allowing for interactions with V $\beta$ 17a (refs 30 and 31) could be inefficient. We consider this hypothesis attractive because other class I-gene products seem to be 'nonpermissive' for interactions with V $\beta$ 17a: H-2<sup>q</sup> mice express V $\beta$ 17a predominantly in CD4<sup>+</sup>CD8<sup>+</sup> cells, but do not express self-genes leading to V $\beta$ 17a<sup>+</sup>-deletion in the CD4<sup>+</sup>CD8<sup>+</sup> population (that is, (SWR $\times$ SJL) F<sub>1</sub> mice (H-2<sup>q</sup> $\times$ H-2<sup>s</sup>) do not delete V $\beta$ 17a<sup>+</sup> CD4<sup>+</sup>CD8<sup>+</sup> T cells; unpublished observations). This is most easily explained by postulating that K<sup>q</sup> and D<sup>q</sup> do not allow for interactions with V $\beta$ 17a, so V $\beta$ 17a CD4<sup>+</sup>CD8<sup>+</sup> T cells cannot be positively selected. We therefore suggest that the intrinsic lack of affinity of a certain TCR V $\beta$  gene for particular MHC molecules may sometimes 'skew' the developing TCR repertoire and generate an apparent rather than a real preference for recognition of other MHC glycoproteins. □

ATRIAL natriuretic peptide (ANP) is a polypeptide hormone whose effects include the induction of diuresis, natriuresis and vasorelaxation<sup>1</sup>. One of the earliest events following binding of ANP to receptors on target cells is an increase in cyclic GMP concentration, indicating that this nucleotide might act as a mediator of the physiological effects of the hormone<sup>2,3</sup>. Guanylate cyclase exists in at least two different molecular forms: a soluble haem-containing enzyme consisting of two subunits<sup>4,5</sup> and a non-haem-containing transmembrane protein having a single subunit<sup>6</sup>. It is the membrane form of guanylate cyclase that is activated following binding of ANP to target cells<sup>3,7,8</sup>. We report here the isolation, sequence and expression of a complementary DNA clone encoding the membrane form of guanylate cyclase from rat brain. Transfection of this cDNA into cultured mammalian cells results in expression of guanylate cyclase activity and ANP-binding activity. The ANP receptor/guanylate cyclase represents a new class of mammalian cell-surface receptors which contain an extracellular ligand-binding domain and an intracellular guanylate cyclase catalytic domain.

Using as probe a cDNA encoding the membrane form of guanylate cyclase from the sea urchin *Arbacia punctulata*<sup>6</sup>, we isolated partial-length putative guanylate cyclase clones from

FIG. 1 Nucleotide sequence and predicted amino acid sequence of rat brain guanylate cyclase cDNA. Nucleotides and amino acids are numbered on the left. Putative signal and transmembrane sequences are underlined, as is the polyadenylation signal. Six potential N-glycosylation sites in the putative extracellular domain are indicated by dashed lines under the amino-acid sequences. The six cysteine residues in the putative extracellular domain are boxed, as are the initiation codon, two upstream ATG sequences and four upstream stop codons.

METHODS. An oligo(dT)-primed, size-selected (>2 kilobases) library was constructed in phage  $\lambda$ gt11, using mRNA from adult rat brain. Partial-length guanylate cyclase cDNA clones were isolated from human cDNA libraries (D.G.L. *et al.*, submitted) using a sea urchin guanylate cyclase cDNA probe<sup>6</sup>. These partial-length cDNA inserts were then used as probes to screen the amplified rat brain  $\lambda$ gt11 library, grown in *Escherichia coli* Y1088 cells. Plaques were transferred to nylon filters and hybridized to random-primed, radiolabelled probes in 2 $\times$ SSC, 0.1% SDS, 5 $\times$ Denhardt's solution, 100  $\mu$ g ml<sup>-1</sup> salmon sperm DNA, at 65 $^{\circ}$ C; filters were washed with 2 $\times$ SSC, 0.1% SDS at 65 $^{\circ}$ C. The longest clone obtained was chosen for sequence analysis. The two cDNA fragments obtained by *Eco*RI digestion of the  $\lambda$ gt11 clone were subcloned into the *Eco*RI site of Bluescript KS<sup>+</sup> (Stratagene) for restriction mapping, then the appropriate restriction fragments were subcloned into M13mp18 and M13mp19 for dideoxy sequencing using Sequenase (United States Biochemical). In addition, deletions were made from the 3' end of the 5' 1.2-kilobase *Eco*RI fragment in Bluescript, as a portion of this fragment lacked convenient restriction sites for subcloning into M13. The Erase-a-Base kit (Promega) was used for the exonuclease III/SI nuclease treatments. Single-stranded templates for sequencing were rescued from the deletion clones in Bluescript using M13K07 as helper phage.

FIG. 2 Alignment of deduced amino-acid sequences of the membrane form of guanylate cyclase from rat brain with a, the bovine ANP-C receptor<sup>16</sup>; b, the murine PDGF receptor<sup>17</sup>; c, bovine soluble guanylate cyclase<sup>19</sup> and yeast adenylate cyclase<sup>20</sup>; d, the membrane form of guanylate cyclase from the sea urchin *Arbacia punctulata*<sup>6</sup>. The entire sequence of the mature rat guanylate cyclase is shown in a-c. Boxed residues represent the putative transmembrane domains (a), the 33 residues most highly conserved among protein kinases<sup>18</sup> (b), and sequences extending beyond the kinase-like domain (d). Regions of identity are indicated by asterisks.

human cDNA libraries (D.G.L. *et al.*, manuscript in preparation). These clones were used in turn, to probe a size-selected rat brain cDNA library to isolate a cloned cDNA containing the entire coding region of guanylate cyclase.

The nucleotide and deduced amino-acid sequences of the guanylate cyclase cDNA are shown in Fig. 1. An open reading frame encoding 1,057 amino acids is preceded by an in-frame stop codon and is flanked by 227 base pairs (bp) and 535 bp of 5' and 3' untranslated sequences respectively. Hydrophobic analysis predicts an amino-terminal signal sequence and a single transmembrane domain that divides the protein into a 441-amino-acid extracellular domain and a 567-amino-acid intracellular domain. Using an algorithm for prediction of the signal cleavage site<sup>9</sup>, residue 29 is expected to represent the amino terminus of the mature protein, which would have a relative molecular mass ( $M_r$ ) of 115,852 and an isoelectric point of 6.33. Taking into account post-translational processing known to occur in guanylate cyclase<sup>10,11</sup>, the predicted  $M_r$  is consistent with estimates of 120,000–180,000 (120K–180K) for membrane forms of guanylate cyclase reported in the literature<sup>10–13</sup>. Six cysteine residues and six potential N-glycosylation sites are present in the extracellular domain.

Further analysis of the deduced amino-acid sequence of the guanylate cyclase cDNA indicates that it may be divided into three potential functional domains (Fig. 2a–c). The extracellular domain of the rat cell membrane guanylate cyclase is 33% identical with the bovine ANP-clearance (ANP-C) receptor, an ANP-binding protein that is apparently not coupled to activation of guanylate cyclase or to the biological effects of ANP (refs 14–16) (Fig. 2a). The ANP-C receptor consists of an extracellular ANP-binding domain, a transmembrane domain and a short cytoplasmic tail<sup>16</sup>; it has been suggested that the function of this protein is to clear excess ANP from the circulation<sup>14</sup>. The five cysteine residues of the ANP-C receptor are conserved guanylate cyclase.

As noted earlier for guanylate cyclase from sea urchin<sup>6</sup>, the intracellular domain is related to the catalytic domain of protein kinases, although protein kinase activity has not yet been detected. A 256-amino acid portion of the intracellular domain is 31% identical to the protein tyrosine kinase domain of the platelet-derived growth factor (PDGF) receptor<sup>17</sup> (Fig. 2b). Guanylate cyclase conforms to the protein kinase consensus sequence<sup>18</sup> in 30 out of 33 residues. Exceptions are Ser<sup>502</sup> (Leu, Ile or Val in all known protein kinases), Asn<sup>628</sup> (Asp in all known protein kinases), and Ala<sup>665</sup> (Ser, Thr or Pro at this position in 63 out of 65 protein kinases). In addition, the Gly-X-Gly-X-X-Gly consensus sequence of protein kinases is Gly-X-Gly-X-X-Gly in the rat guanylate cyclase.

The most extensive similarity between the deduced amino-acid sequence of the membrane form of guanylate cyclase and other proteins is found in the carboxyl portion of the intracellular domain. A 253-amino acid sequence in this region is 42% identical to the carboxyl terminus of one of the subunits of a bovine soluble form of guanylate cyclase<sup>19</sup> (Fig. 2c). It is not yet known whether the sequence determined for the soluble enzyme is from a regulatory or catalytic subunit<sup>19</sup>. But only a 77-residue portion of this 253-amino acid region is conserved in guanylate cyclase from the sea urchin *Arbacia punctulata* (see below), which implies that it may not be the guanylate cyclase

catalytic domain. This region of the carboxyl tail has limited (23%) sequence identity with a 193-amino-acid portion of the yeast adenylate cyclase<sup>20</sup> (Fig. 2c); the significance, if any, of this limited similarity is not known.

The deduced amino-acid sequence of rat brain guanylate cyclase is 45% identical to that of the membrane form of guanylate cyclase from the sea urchin *Arbacia punctulata*<sup>6</sup> within a 399-amino acid region of the intracellular domain beginning immediately after the transmembrane domain (Fig. 2d). This region consists primarily of the protein kinase-like domain but also includes 77 amino acids carboxyl to this domain (Fig. 2d). Presumably this highly conserved region includes the guanylate cyclase catalytic domain, whereas the divergent regions may represent regulatory domains.

To confirm that the isolated cDNA encoded a protein with guanylate cyclase activity, we inserted the cDNA in a mammalian expression vector (pSVL) under the control of the SV40 late promoter. Because upstream AUG codons have been reported to reduce the efficiency of translation of messenger

TABLE 1 Particulate guanylate cyclase activity and <sup>125</sup>I-labelled ANP-binding activity of transfected COS-7 cells

COS-7 cells, maintained in Dulbecco's modified Eagle's medium (DME) supplemented with 20 mM HEPES at pH 7.4 with penicillin/streptomycin and 10% fetal bovine serum, were transfected with plasmid DNA using DEAE-dextran<sup>28</sup>. Cells were seeded at  $5 \times 10^6$  cells per 100-mm plate (guanylate cyclase assay) or  $5 \times 10^5$  cells per 35-mm plate (<sup>125</sup>I-labelled ANP binding assay). Cells were fed the day after transfection and assayed for guanylate cyclase activity or <sup>125</sup>I-ANP binding two days after transfection. The guanylate cyclase construct in pSVL (Pharmacia) was prepared as follows. The 5' 1.2-kb *EcoRI* fragment of the guanylate cyclase cDNA was cloned into the *EcoRI* site of Bluescript KS<sup>+</sup>, oriented so that the 5' end of the insert was closest to the *HindIII* site in the polylinker. The 194 bp at the 5' end of the insert were removed by digestion with *HindIII* and *NcoI*, and the 4-kb fragment containing the remainder of the cDNA and the vector was purified by agarose gel electrophoresis and adsorption to glass beads. The DNA was then treated with *S1* nuclease and religated. The extent of the resulting deletion was determined by double-stranded sequencing. The 3' 2.7-kb *EcoRI* fragment of the guanylate cyclase cDNA was then cloned into the *EcoRI* site of the modified plasmid, and its orientation confirmed by restriction analysis. The *SalI/SmaI* fragment containing the guanylate cyclase cDNA with the upstream ATGs removed was then cloned into the *XhoI/SmaI* site of pSVL to create pSVL-GC. For guanylate cyclase assays, 100-mm cultures on ice were washed twice with 5 ml cold HEPES-buffered saline, scraped into 3 ml cold 20 mM HEPES, pH 7.4, 50 mM NaCl, 5 mM EDTA, 1 mM dithiothreitol, and homogenized by passage ten times through a 22-gauge needle. Following centrifugation for 15 min at 5,000g and washing with the same buffer, membrane proteins were solubilized by incubation on ice for 30 min in a solution containing 20 mM HEPES, pH 7.4, 100 mM NaCl, 10% glycerol, 1% Triton X-100, 1 mM dithiothreitol. After centrifugation for 15 min at 5,000g, supernatant fluids were adjusted to equal protein concentrations and incubated for 10 min in the absence or presence of 1  $\mu$ M ANP at 0 °C. Incubation was continued for 30 min at 30 °C after diluting 100  $\mu$ l each sample into a solution containing a final concentration of 20 mM HEPES, pH 7.4, and 1 mM each GTP, MnCl<sub>2</sub> and methyl isobutylxanthine, in a total reaction volume of 250  $\mu$ l. Reactions were stopped by the addition of 750  $\mu$ l 0.5 M perchloric acid and samples were analysed for cGMP by radioimmunoassay after purification of nucleotides by Dowex chromatography<sup>26</sup>. <sup>125</sup>I-labelled ANP binding was measured essentially as described<sup>15</sup>. Cells in 35-mm plates were washed twice with 2 ml DME/0.1% bovine serum albumin (BSA), then incubated in 0.5 ml the same buffer containing 0.5 nM <sup>125</sup>I-labelled rat ANP (2,200 Ci mmol<sup>-1</sup>, NEN) in the absence or presence of 0.5  $\mu$ M unlabelled rat ANP (Sigma) for 20 min at 37 °C. After five 1-ml washes with HBSS/0.1% BSA, cells were solubilized in 1 ml 0.5 M NaOH and the radioactivity determined. All determinations were in triplicate (nonspecific binding was ~5,000 c.p.m. in each case).

RNA<sup>21,22</sup>, 194 bp of 5' untranslated sequences were removed from the cDNA before its insertion into pSVL; this resulted in the deletion of the two ATG sequences 5' to the initiation site (see Fig. 1 and Table 1 legend). This modification of the cDNA was found to enhance expression of guanylate cyclase about tenfold in transfected mammalian cells (data not shown). COS-7 cells were transfected with the guanylate cyclase expression plasmid (pSVL-GC) or with pSVL, and a particulate fraction was isolated from the cells and assayed for enzyme activity. The activity of membrane-associated guanylate cyclase was increased by about 40-fold in cells transfected with pSVL-GC (Table 1), which is consistent with the clone encoding guanylate cyclase. ANP stimulated guanylate cyclase activity about threefold in detergent extracts of both control cells and cells expressing the cloned guanylate cyclase (Table 1).

The cloned guanylate cyclase also functions as an ANP-receptor (Table 1). Cells transfected with pSVL-GC specifically bound about nine times more <sup>125</sup>I-labelled ANP than cells transfected with pSVL alone. <sup>125</sup>I-labelled ANP bound with high affinity and the expected specificity (half-maximal inhibition of binding of 0.4 nM <sup>125</sup>I-labelled ANP occurred at about 3 nM unlabelled ANP or 100 nM unlabelled atriopeptin I; data not shown). To verify that guanylate cyclase is acting as an ANP-receptor, we used <sup>125</sup>I-labelled ANP in cross-linking experiments (Fig. 3). Transfected cells were incubated with <sup>125</sup>I-labelled ANP with or without excess unlabelled ANP. After cross-linking and SDS-polyacrylamide gel electrophoresis under reducing conditions, a single band migrating with *M<sub>r</sub>* 130K was evident from

FIG. 3 Cross-linking of <sup>125</sup>I-labelled ANP to transfected COS-7 cells. Transfections are described in the legend to Table 1. Binding and cross-linking have been described previously<sup>15</sup>. Cells were washed 3 times with 2 ml Hanks' balanced salt solution (HBSS), then incubated for 1 h at room temperature in 1 ml HBSS containing 0.5 nM <sup>125</sup>I-labelled ANP (2,200 Ci mmol<sup>-1</sup>) in the absence (a, c) or presence (b, d) of 0.5 μM unlabelled ANP. 1 ml HBSS containing 2 mM disuccinimidyl suberate was added to a final concentration 1 mM and the incubation continued for 30 min. Cells were then washed with 2 ml HBSS and solubilized in 400 μl hot (95 °C) Laemmli sample buffer<sup>28</sup>, of which 150 μl was heated at 95 °C in the presence of 7.5 μl 2-mercaptoethanol and analysed by electrophoresis on a 7.5% SDS-polyacrylamide gel<sup>29</sup>, followed by drying and autoradiography. Positions of molecular weight markers are shown on the right; the top and bottom of the separating gel are indicated by arrowheads. a, b, Cells transfected with pSVL; c, d, cells transfected with pSVL-GC.

the cells transfected with pSVL-GC. This band was not seen in the presence of an excess of non-radioactive ANP or in cells transfected with pSVL. The mobility of this radioactive band coincides with that previously reported for the high-molecular weight ANP receptor<sup>12,15,23,24</sup>. Thus the guanylate cyclase cDNA encodes a protein having both guanylate cyclase and ANP-binding activities.

In conclusion, we have isolated and sequenced a cDNA clone for the membrane form of guanylate cyclase from rat brain. From the cDNA sequence we predict a protein divided by a single transmembrane domain into an amino-terminal extracellular ANP-binding domain, and a carboxyl-terminal intracellular catalytic domain (Fig. 4). The intracellular domain is homologous both with protein kinases and to a subunit of the soluble form of guanylate cyclase, whereas the extracellular domain is homologous with a low-molecular weight ANP receptor. Expression of the cDNA produces a protein with both ANP-binding and guanylate cyclase activity.

Previous cross-linking experiments indicated that the membrane form of guanylate cyclase in *Arbacia punctulata* could function as a receptor for egg-associated peptides which activate sperm respiration and motility<sup>25</sup>; one of the earliest effects of these egg peptides on spermatozoa is the stimulation of cyclic GMP synthesis<sup>26,27</sup>. But functional expression of the cloned sea urchin enzyme has not yet been obtained in mammalian cells or in *Xenopus* oocytes<sup>6</sup>, apparently because of a lack of proper post-translational modification. It has not been possible, therefore, to test directly whether the enzyme serves as a receptor. Several groups have also reported the co-purification of high-molecular weight ANP receptors with active guanylate cyclase<sup>12,13,24</sup>, but it is not clear whether the two activities reside within the same molecule<sup>12</sup>. Here we have demonstrated directly that the membrane form of guanylate cyclase functions as a receptor. The ANP receptor/guanylate cyclase we describe may represent, by analogy with the growth factor receptor/protein

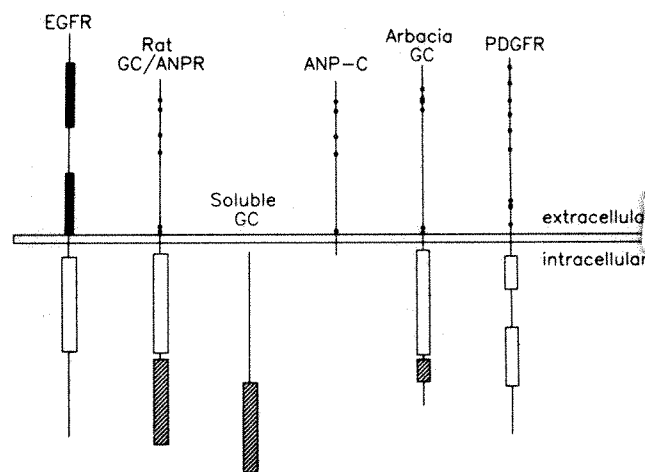

FIG. 4 Topology of members of the guanylate cyclase/ANP receptor family and the growth factor receptor/protein tyrosine kinase family. Drawn to scale are representations of the epidermal growth factor receptor (EGFR)<sup>30</sup>, the membrane forms of guanylate cyclase from rat (rat GC/ANPR) and from the sea urchin *Arbacia punctulata* (Arbacia GC)<sup>6</sup>, a subunit of the soluble form of guanylate cyclase (soluble GC)<sup>19</sup>, the ANP-C receptor (ANP-C)<sup>16</sup>, and the platelet-derived growth factor receptor (PDGFR)<sup>17</sup>. Drawing modelled after ref. 17. Individual cysteine residues are indicated by black circles in the extracellular domains of each protein, except in the case of the EGF receptor, in which the cysteine-rich domains are indicated by black boxes. Protein kinase domains (EGFR and PDGFR) and protein kinase-like domains (rat GC/ANPR, Arbacia GC) are indicated by open boxes. Areas of sequence similarity between the soluble and membrane forms of guanylate cyclase are indicated by hatched boxes.

tyrosine kinases, a member of a diverse family of cell-surface receptors. This family is unique with regard to the regulation of cyclic nucleotides, in that cGMP is formed directly by the receptor protein in response to the binding of an agonist. □

## Molecular cloning and characterization of an insulin-regulatable glucose transporter

David E. James, Marilyn Strube & Mike Mueckler

Department of Cell Biology, Box 8101, Washington University Medical School, 660 South Euclid Ave., St Louis, Missouri 63110, USA

A MAJOR mechanism by which insulin stimulates glucose transport in muscle and fat is the translocation of glucose transporters from an intracellular membrane pool to the cell surface<sup>1–5</sup>. The existence of a distinct insulin-regulatable glucose transporter was suggested by the poor cross-reactivity between antibodies specific for either the HepG2 or rat brain glucose transporters and the rat adipocyte glucose transporter<sup>6,7</sup>. More direct evidence was provided by the production of a monoclonal antibody (mAb 1F8) specific for the rat adipocyte glucose transporter that immunolabels a species of relative molecular mass 43,000 (43K) present only in tissues that exhibit insulin-dependent glucose transport<sup>8</sup>, suggesting that this protein may be encoded by a different gene from the previously described mammalian glucose transporters<sup>9–13</sup>. This antibody has been used to immunoprecipitate a 43K protein that was photoaffinity-labelled with cytochalasin B in a glucose displaceable way, and to immunolabel a protein in the plasma membrane of rat adipocytes, whose concentration was increased at least fivefold after cellular insulin exposure. Here we describe the cloning and sequencing of cDNAs isolated from both rat adipocyte and heart libraries that encode a protein recognized by mAb 1F8, and which has 65% sequence identity to the human HepG2 glucose transporter<sup>9</sup>. This cDNA hybridizes to an mRNA present only in skeletal muscle, heart and adipose tissue. Our data indicate that this cDNA encodes a membrane protein with the characteristics of the translocatable glucose transporter expressed in insulin-responsive tissues.

Several clones were isolated from a rat adipocyte and a rat heart cDNA library by low stringency hybridization using a fragment of the HepG2 glucose transporter cDNA as the probe. A 2,086-base pair (bp) consensus sequence (the 'IRGT sequence') compiled from four independent clones obtained from both libraries is shown in Fig. 1a. This sequence includes the complete coding region for a protein that shares sequence similarity with the HepG2 glucose transporter (Fig. 1b). The initiation codon was assigned to the first ATG triplet (beginning at position 154) downstream of an in-frame termination codon (TGA) beginning at position 133. An open reading frame extends

from this ATG triplet to position 1,680 that codes for a 509-amino acid polypeptide with a predicted relative molecular mass ( $M_r$ ) of 54,860. This value is in reasonable agreement with the estimated size (38K) of the deglycosylated transporter immunolabelled with mAb 1F8 (data not shown). The difference between the predicted and measured  $M_r$  values is similar to the difference between these values for the HepG2 glucose transporter, consistent with the anomalous migration of membrane proteins during SDS-PAGE<sup>9</sup>. Several clones were isolated from the adipocyte library that contained deletions in the 5' region of the mRNA compared to the IRGT sequence. The deleted regions were flanked by extremely GC-rich sequences. Thus, the deletions probably resulted from excision of hairpin loops formed during construction of the library.

The deduced amino-acid sequence of IRGT is 65.2% identical to that of the HepG2 glucose transporter (Fig. 1b). The sequence identity between the two proteins is particularly strong within the predicted transmembrane segments, with the notable exception of segment 3 (amino-acid residues 112–132 in the IRGT sequence, Fig. 1). Interestingly, there is little sequence homology between the IRGT (Fig. 1a), the HepG2 glucose transporter<sup>9</sup> and the liver glucose transporter<sup>12,13</sup> within this particular domain. There are considerable differences in the sequences of the HepG2 glucose transporter and IRGT within the predicted soluble domains of the HepG2 transporter<sup>9</sup>, particularly those encompassing the N and C terminus and the large, central, cytoplasmic loop. IRGT shares the putative glycosylation site (Asn 57) present in the HepG2 transporter (Asn 45) within a proposed exofacial loop after the first transmembrane segment. IRGT also contains the putative photoaffinity-labelling cytochalasin B-binding site (Trp 428) corresponding to Trp 412 in the HepG2 sequence<sup>14,15</sup>. The hydropathy plot of the IRGT protein sequence, deduced using the method of Kyte and Doolittle<sup>16</sup>, is nearly superimposable on that of the HepG2 glucose transporter<sup>9</sup> (data not shown), suggesting that these two proteins have very similar two-dimensional topologies with respect to the membrane. IRGT has slightly larger N-terminal, C-terminal and glycosylated loop domains compared to the HepG2 glucose transporter however.

RNA was transcribed from a 2,086-bp IRGT cDNA construction and translated in an *in vitro* rabbit reticulocyte lysate system. The primary translation product synthesized in the absence of microsomes had a slightly reduced mobility on SDS-polyacrylamide gels (apparent  $M_r$  = 39K) relative to the HepG2 translation product (apparent  $M_r$  = 37K), in reasonable agreement with the predicted difference in the relative molecular masses of the two proteins. Addition of dog pancreatic microsomes to the translation system decreased the mobility of both the IRGT (apparent  $M_r$  = 43K) and HepG2 (apparent  $M_r$  = 40K) proteins (Fig. 2) consistent with core glycosylation upon cotranslational

## *b*

NATURE • VOL 338 • 2 MARCH 1989

FIG. 1 a, Nucleotide sequence of IRGT cDNA and the deduced amino-acid sequence of the insulin-regulatable glucose transporter. The nucleotide sequence presented was compiled from the four clones whose sequences were identical in the overlapping regions. The two adipocyte clones encompassed residues 1–1,450 and 241–2,086. The two heart clones encompassed residues 141–1,212 and 717–1,944. Amino-acid residues are numbered above the sequence and nucleotides are numbered below. b, Deduced amino-acid sequences of the HepG2 glucose transporter and IRGT are aligned for comparison. The amino acids are indicated in the one-letter code. Regions of identity between the HepG2 glucose transporter and IRGT amino-acid sequences are indicated by a dash. Gaps have been introduced to optimize the alignment.

**METHODS.** Phage plaques ( $2 \times 10^6$ ) from both rat adipocyte and rat heart cDNA libraries in  $\lambda$ gt11 were screened under low stringency hybridization conditions (39 °C in 50% formamide,  $5 \times$  SSPE, 0.1% SDS,  $5 \times$  Dehnhardt's 250  $\mu$ g ml<sup>-1</sup> salmon sperm DNA) using a <sup>32</sup>P-labelled EcoRI fragment (from pGT25S ref. 9) of the HepG2 glucose transporter. Filters were washed at room temperature in  $1 \times$  SSC, 0.5% SDS and then at 42 °C in  $0.1 \times$  SSC, 0.5% SDS. Positive clones were plaque-purified and the cDNA inserts were sized after EcoRI digestion of the mini-prep DNA. Four clones (two from each library) were selected for further characterization. The inserts were subcloned into the EcoRI sites of M13mp18 and mp19 and were sequenced in both strands according to a modified version<sup>24</sup> of the Sanger method<sup>25</sup>. The sequence data were compiled by the computer-assisted method of Staden<sup>26</sup>. The insert DNAs were sequenced completely.

insertion of the protein into microsomes. Subsequent digestion with endoglycosidase H indicated that IRGT and the HepG2 glucose transporter were core-glycosylated to the same extent during insertion into microsomes (data not shown). The apparent  $M_r$  of the core glycosylated translation product of IRGT (Fig. 2) was similar to the  $M_r$  of the protein in fat and muscle immunolabelled by mAb 1F8 (Fig. 3). The IRGT translation product, but not that of the HepG2 glucose transporter RNA, was specifically immunoprecipitated using mAb 1F8 (Fig. 2). A polyclonal antibody (R820) was prepared by immunizing rabbits with a peptide corresponding to residues 498–509 within the predicted sequence of IRGT (see Fig. 1a). This antiserum also specifically immunoprecipitated the IRGT translation product (Fig. 2). Polyclonal and monoclonal antibodies raised against the human erythrocyte glucose transporter immunoprecipitated the HepG2 glucose transporter translation product but not that of IRGT (data not shown).

In contrast to the tissue distribution of the HepG2 glucose transporter<sup>17</sup> or human liver-like glucose transporter<sup>10</sup> mRNAs, IRGT mRNA was detected at relatively high levels in brown and white adipose tissue, heart and red and white skeletal muscle (Fig. 3a). There was no detectable hybridization to brain, liver, or HepG2 RNA. Rat kidney RNA had a weak signal, presumably due to contamination with renal brown fat during RNA purification. An RNA transcript was also present in 3T3-L1 adipocytes but not in pre-adipocytes (Fig. 3a). Qualitatively, the tissue distribution of IRGT mRNA was identical to the distribution of the protein as determined by immunoblotting with mAb 1F8 (Fig. 3c) or the peptide-specific antiserum, R820 (Fig. 3d). In addition, both mAb 1F8 (Fig. 4b) and R820 (Fig. 4a) immunolabelled a protein of about 45K in 3T3-L1 adipocytes but not in 3T3-L1 fibroblasts. The differences in tissue abundance of the 43K protein immunolabelled with these antisera (brown adipose tissue > heart > red muscle > white adipose tissue and white muscle) parallel the heterogeneity in *in vivo* insulin-stimulated glucose utilization rates that are observed among these tissues<sup>18–20</sup>. In contrast, using an anti-human erythrocyte glucose transporter antibody, the highest labelling among rat tissues was found in brain (Fig. 3b) and a similar concentration of this HepG2-like transporter was detected in both 3T3-L1 fibroblasts and adipocytes (Fig. 4b). Relatively weak immunolabelling was observed with the anti-human erythrocyte glucose transporter antibody in muscle, heart and fat. Interestingly, of six heart clones and seven adipocyte clones

FIG. 2 Translation of IRGT RNA in a reticulocyte cell-free system. A 2,086-bp IRGT cDNA was constructed by ligation of unique EcoRI-ScaI fragments, derived from the two adipocyte clones described in the Fig. 1 legend, at the ScaI site. The resulting construct was subcloned into the EcoRI site of Bluescribe plasmid. IRGT and HepG2 GT mRNA<sup>27</sup> were synthesized *in vitro* using T7 or SP6 RNA polymerase, respectively, and then translated in a reticulocyte lysate system in the presence of <sup>35</sup>S-methionine as previously described<sup>27</sup>. Lysates or pelleted rough microsomes were analysed by SDS-PAGE using an 8% resolving gel. Lane 1, 25  $\mu$ l of lysate with HepG2 glucose transporter mRNA; lane 2, 25  $\mu$ l of lysate with IRGT mRNA; lane 3, 25  $\mu$ l of lysate with HepG2 glucose transporter mRNA translated in the presence of rough microsomes; lane 4, 25  $\mu$ l of lysate with IRGT mRNA translated in the presence of rough microsomes. IRGT RNA was translated in the presence of dog pancreatic microsomes, the microsomes were pelleted, washed, solubilized with 1% SDS and diluted (1:10, v:v) with PBS containing 1% Triton X-100 and then divided into two equal aliquots: immunoprecipitation using mAb 1F8 (ref. lane 6), immunoprecipitation using R820 antiserum (lane 8). HepG2 glucose transporter RNA was translated and immunoabsorbed using mAb 1F8 (lane 5) or R820 (lane 7). The relative migration of relative molecular mass standards is indicated on the left.

that were isolated using the HepG2 glucose transporter cDNA, none corresponded to the HepG2-type glucose transporter<sup>9,10</sup>. Thus, the HepG2-type transporter is probably expressed at low levels, if at all, in insulin-regulatable tissues. The emergence of the IRGT mRNA and protein after differentiation of 3T3-L1 fibroblasts into adipocytes is consistent with the induction of a highly sensitive and responsive hexose transport system under these conditions<sup>21,22</sup>. These data indicate that 3T3-L1 cells may provide a unique model for studying the factors involved in regulating expression of the insulin-regulatable glucose transporter as well as the cellular factors that confer tissue-specific insulin-dependent glucose transport.

Further evidence that IRGT encodes an insulin-regulatable protein is shown in Fig. 4a. The R820 antiserum immunolabelled a protein of similar size to that reported for the adipocyte glucose transporter in the low-density microsomes of untreated rat adipocytes (reviewed in ref. 8). Consistent with previous data obtained using mAb 1F8 (ref. 8), R820 immunolabelled a 43K protein in a plasma membrane fraction from rat adipocytes, the concentration of which was increased about sevenfold upon cellular insulin exposure (Fig. 4a). Similar results have been observed with 3T3-L1 adipocytes (data not shown). These data provide further support for the glucose transporter translocation hypothesis<sup>1,2</sup>. The competition data presented in Fig. 4c indicate

that the epitopes recognized by mAb 1F8 and R820 either overlap or are identical, that the epitope of mAb 1F8 is specific for the C terminus of the protein, and that mAb 1F8 and R820 do recognize the same protein in adipocyte membrane fractions.

Several strands of evidence suggest that IRGT encodes the acutely insulin-responsive glucose transporter: (1) the IRGT protein shares considerable sequence and structural identity with other glucose transporters<sup>9,10,13</sup>, (2) mAb 1F8 immuno-

precipitates the IRGT protein; (3) the tissue distribution of the IRGT protein parallels the acute insulin responsiveness with respect to glucose transport of various tissues *in vivo*; (4) insulin stimulates the translocation of the IRGT protein from a low-density microsomal fraction to the plasma membrane in rat and 3T3-L1 adipocytes; and (5) the differentiation of 3T3-L1 fibroblasts into adipocytes is accompanied by the appearance of IRGT mRNA and protein. Definitive evidence that the cDN/ clone described in this study encodes a protein that transport

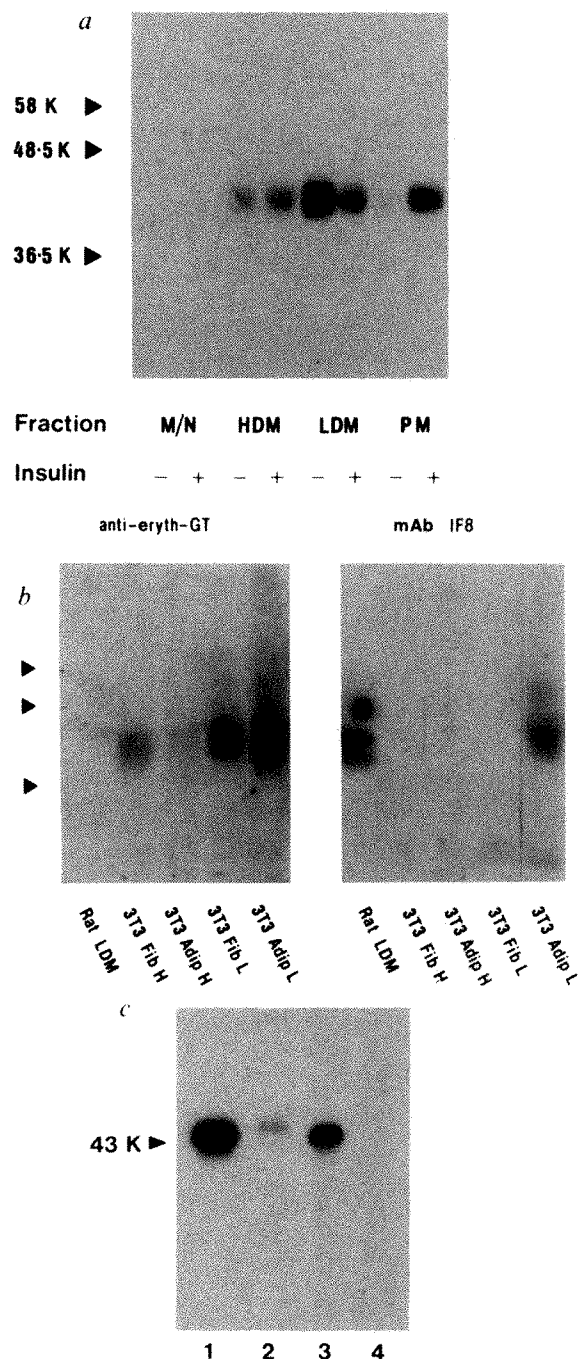

FIG. 3 Tissue distribution of IRGT mRNA and protein. *a*, Total RNA isolated from various rat tissues probed with IRGT cDNA. Abbreviations: 3T3-L1 fibroblasts, Fib; 3T3-L1 adipocytes, Adip; rat white adipose tissue, WAT; rat brown adipose tissue, BAT; rat red skeletal muscle, RM; rat white skeletal muscle, WM. *b*, Rat tissues were homogenized in PBS containing 1% Triton X-100. Total tissue protein (100 µg) from rat tissues were analysed by SDS-PAGE followed by immunoblotting using a polyclonal antisera against the human erythrocyte glucose transporter<sup>9</sup>. Immunoreactive glucose transporter was visualized using <sup>125</sup>I-labelled Protein A (Amersham). *c*, Total protein extracts (100 µg) from rat tissues were immunoblotted using mAb 1F8. Immunolabelled bands were visualized using <sup>125</sup>I-labelled sheep anti-mouse IgG (Amersham). *d*, Total protein extracts (100 µg) from rat tissues and 1 µg of purified human erythrocyte glucose transporter (hGT) were immunoblotted using a polyclonal antisera (R820) specific for a peptide derived from the C-terminal sequence of IRGT. Iodo-labelled Protein A was used to visualize the immunolabelled proteins.

**METHODS.** Total RNA was isolated (*a*) from rat tissues using the guanidinium, CsCl procedure<sup>28</sup>. The samples (50 µg of each) were electrophoresed on a

formaldehyde-agarose gel (1.2%) and then blotted and fixed onto a nylon membrane. The blot was hybridized to IRGT cDNA labelled with <sup>32</sup>P by nick-translation, washed, and exposed to Kodak XAR-5 film as previously described<sup>19</sup>. RNA markers are in an adjacent lane. For *d*, a 12-amino-acid peptide (Thr-Glu-Leu-Glu-Tyr-Leu-Gly-Pro-Asp-Glu-Asn-Asp), corresponding to the 12 terminal amino acids within the C terminus of IRGT (Fig. 1a) was synthesized by the Protein Chemistry laboratory at Washington University School of Medicine. A cysteine was included at the N terminus of the peptide to facilitate coupling of 12.5 mg of the peptide to keyhole limpet haemocyanin (KLH) (40 mg), using the cross-linking reagent *m*-maleimidobenzoyl-*N*-hydroxysuccinimide ester (Pierce, Rockford, Illinois), as previously described<sup>29</sup>. The peptide-KLH conjugate was emulsified in Freund's complete adjuvant and injected at multiple sites intradermally (500 µg) into three New Zealand white rabbits. The rabbits were boosted at three-week intervals with the peptide conjugate (300 µg) emulsified in incomplete adjuvant and bleeds were obtained two weeks after this boost. Sera obtained from all three rabbits tested positive by immunoblotting rat adipocyte subcellular fractions. One rabbit serum (R820) was selected for further study as described here.

**FIG. 4** IRGT encodes an insulin-regulatable protein. *a*, Immunoblot using polyclonal antisera (R820) of subcellular membrane fractions (50  $\mu$ g) obtained from rat adipocytes after incubation in the absence or presence of insulin ( $10^{-8}$  M) for 15 min: mitochondria/nuclei (M/N), high-density microsomes (HDM), low-density microsomes (LDM) and plasma membranes (PM). *b*, Immunoblot of 3T3-L1 fibroblasts and 3T3-L1 adipocyte membrane fractions (100  $\mu$ g) using either a polyclonal antibody specific for the human erythrocyte glucose transporter (anti-eryth GT)<sup>9</sup> or mAb 1F8. Confluent plates of either 3T3-L1 fibroblasts or adipocytes were homogenized in a buffer containing 20 mM HEPES, 250 mM sucrose, 1 mM EDTA, pH 7.4. Total membrane pellets were layered onto a 1.12 M sucrose cushion, and centrifuged at 100,000*g* in an SW 41 rotor (Beckman). This procedure resolved membrane fractions above (L) and below (H) the sucrose cushion, of similar protein concentration for fibroblasts and adipocytes. Rat LDM (50  $\mu$ g) was electrophoresed in an adjacent lane for comparison. *c*, Rat adipocyte low-density microsomes (20  $\mu$ g) were immunoblotted with a polyclonal antisera, R820, at a dilution of 1:500 (lane 1), or with R820 (1:500) in the presence of mAb1F8 (20  $\mu$ g ml<sup>-1</sup>, lane 2), with mAb1F8 alone (2  $\mu$ g ml<sup>-1</sup>, lane 3) or with mAb1F8 (2  $\mu$ g ml<sup>-1</sup>) in the presence of R820 (1:20, lane 4). Immunoreactive species were detected using <sup>125</sup>I-labelled Protein A (lanes 1 and 2) or <sup>125</sup>I-labelled sheep anti-mouse IgG (lanes 3 and 4).

glucose will require functional expression. It is interesting that several bacterial proton symporters that do not seem to transport glucose also have significant homology with the HepG2 glucose transporter<sup>23</sup>. Thus, it is conceivable that IRGT represents a member of this gene family, whose function involves the transport of a substrate other than glucose. In any case, the overall phenotype of IRGT suggests that this protein has an important role in insulin action. A gene encoding an insulin-regulatable glucose transporter that is expressed only in muscle and fat would be an obvious target for a genetic defect causing predisposition toward insulin-resistant states such as non-insulin-dependent diabetes mellitus. □

## Double-strand breaks at an initiation site for meiotic gene conversion

Hong Sun, Douglas Treco, Neil P. Schultes & Jack W. Szostak

Department of Molecular Biology, Massachusetts General Hospital, Boston, Massachusetts 02114, USA

It has been proposed that the initiation of meiotic recombination involves either single-strand or double-strand breaks in DNA<sup>1-3</sup>. It is difficult to distinguish between these on the basis of genetic evidence because they give rise to similar predictions<sup>4-6</sup>. All models invoke initiation at specific sites to explain polarity, which is a gradient in gene conversion frequency from one end of a gene to the other. In the accompanying paper<sup>7</sup> we describe the localization of an initiation site for gene conversion to the promoter region of the *ARG4* gene of the yeast *Saccharomyces cerevisiae*. Here, we show that a double-strand break appears at the *ARG4* recombination initiation site at the time of recombination, and that the broken DNA molecules end in long single-stranded tails.

FIG. 1 *a*, Map of plasmid p(SPO13)2 (ref. 27) linearized with *Sph*I. The location of the centromere and yeast genes are shown under it. The three meiosis-specific cleavage sites are indicated by arrows. *R* and *L* represent probes used to detect cleaved fragments. The open box represents 15 kb of DNA from the yeast *ARG4* locus. *b*, Time course of undigested plasmid DNA through meiosis. The lowest, most intense band (I) represents supercoiled monomers, band *I<sub>d</sub>* is supercoiled dimer circles, band II is relaxed monomer circles and the transient band III is due to linearized plasmid molecules. The identity of the bands was established by two-dimensional electrophoresis<sup>28</sup> and comparison with known markers.

**METHODS.** Cells of strain NKY278 (*MATa/MATα*, *LYS2::HO/lys2::HO*, *lys2/lys2*, *ura3/ura3*) carrying plasmid p(SPO13)2 were grown mitotically in YP-acetate medium (1% yeast extract, 2% bacto-peptone, 1% potassium acetate) and transferred to sporulation medium (1% potassium acetate) to start meiosis. Aliquots were removed every hour, frozen, and DNA prepared as described<sup>29</sup>. The DNA was analysed by electrophoresis on a 0.4% agarose gel, transferred to Nytran membrane and detected with a <sup>32</sup>P-labelled pBR322 (vector-specific) probe.

We have examined the DNA of a yeast plasmid containing a meiotic recombination initiation site for changes related to recombination as the cell progresses through meiosis. The plasmid carries a 15-kilobase (kb) fragment of DNA that includes the *ARG4* gene (Fig. 1*a*). The diploid yeast strain we used is a derivative of SK-1 (ref. 8), which undergoes a rapid and synchronous meiosis upon transfer to sporulation medium.

Total DNA was extracted from yeast cells collected at hourly intervals after transfer to sporulation medium and the structure of the plasmid DNA was analysed by Southern blotting<sup>9</sup>. Figure 1*b* shows that the plasmid exists predominantly as supercoiled monomers immediately after transfer to sporulation medium, with some relaxed monomer and various dimer forms. All of these persist through meiosis. As meiosis proceeds however, a new band appears with the mobility of full-length linear plasmid DNA. This band is visible three hours after transfer to sporulation medium, peaks in intensity at four hours, and has decreased

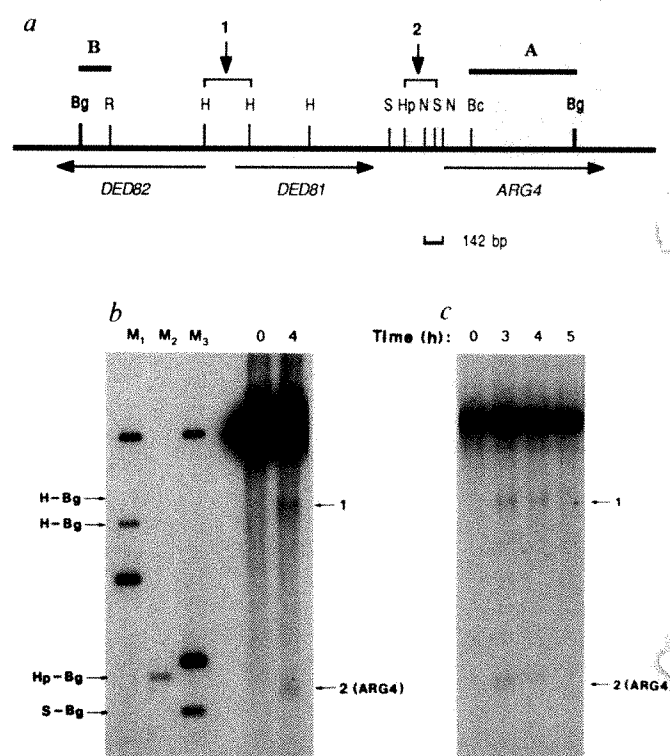

FIG. 2 *a*, Partial restriction map of the *ARG4* region. Restriction sites in and near *ARG4* and two adjacent essential genes, *DED81* and *DED82*, represented by arrows covering their open reading frames. *A* and *B* represent restriction fragments used as probes. *Bc*, *Bc1*, *Bg*, *Bg1*, *R*, *EcoR*, *H*, *HindIII*, *Hp*, *HpaI*, *N*, *NspHI*, *S*, *SspI*. The 142-bp *NspHI* fragment which was deleted to remove the initiation site is shown below. *b*, Higher resolution mapping of meiosis-specific cleavage sites 1 and 2. DNA from mitotic cells (0 hours), and cells four hours into meiosis was cleaved with *Bgl*I, electrophoresed on a 0.7% agarose gel, blotted and probed with probe *A*. The labelled fragments in the marker lanes extend from the right-hand *Bgl*I site to the restriction sites indicated. Fragments labelled 1 and 2 are seen in the lane containing the 4-h sample but not the 0-h sample lane, and represent cleavage of the *Bgl*I fragment DNA at either site 1 or site 2 respectively. The strongly hybridizing band appearing in both the 0- and 4-h sample lanes represents intact 5-kb *Bgl*I fragment DNA. The *ARG4* cleavage site maps between the *Hpa*I and *Ssp*I restriction sites in the *ARG4* promoter region. The locations of cleavage sites 1 and 2 were confirmed by mapping from the other side of the break using probe *B* (data not shown). *c*, Analysis of chromosomal DNA from strain NKY278 before (0 h) and during (3, 4 and 5 h) meiosis. Cleavages at sites 1 and 2 are still visible, as represented by fragments 1 and 2.

in intensity by five hours. The linear DNA appears at the same time (2.5–5 h) as commitment to meiotic recombination occurs in SK-1 and its derivative strains<sup>10–11</sup>. In addition, we find that the products of recombination between two restriction site mutations in the *LEU2* gene<sup>12</sup> in an SK-1 strain background are first detectable at four hours, but do not reach their maximal level until five to six hours (data not shown).

We used restriction enzyme digestion to show that the linear plasmid molecules are generated by cleavage at specific sites and to map these sites. Our data indicate that there are three distinct subpopulations of linear plasmid molecules, each resulting from a double-strand break at one of three sites (1, 2 and 3 in Fig. 1*a*). Each subpopulation consists of about 0.5–1% of the total plasmid population, as determined from comparison with serial dilutions of genomic DNA.

More detailed mapping of the break sites (Fig. 2) revealed that site 2 is located within a 261-base pair (bp) region between the *Hpa*I and *Ssp*I sites immediately 5' to the *ARG4* coding region. Both the *ARG4* transcriptional promoter<sup>13</sup> and the

FIG. 3 Effect of deleting the *ARG4* initiation site on the meiosis-specific double-strand break. Plasmid p(SPO13)2- $\Delta$ 142 is identical to p(SPO13)2, except that 142-bp are deleted in the *ARG4* promoter region that removes the recombination initiation site<sup>7</sup>. DNA was prepared from cells containing either this plasmid or its wild-type parent (w.t.), before and during meiosis. Samples were digested with *Sph*I, electrophoresed on a 0.5% agarose gel and the fragments detected with probe R (Fig. 1a). The top intense band represents full-length (25 kb) linear plasmid. The three fainter bands are 19, 17 and 10 kb long, and arise from cleavage at sites 1, 2 and 3 respectively. The break in the *ARG4* promoter region (site 2) is absent in the deletion plasmid.

initiation site for meiotic gene conversion (see Fig. 2 in ref. 7) lie in this region. Break site 1 is located within a 450-bp region between two *Hind*III sites, which contains promoters for two divergently transcribed genes, *DED81* and *DED82* (ref. 7; N.P.S. and H.S., unpublished data). Site 3 maps near a functional promoter in the plasmid vector<sup>14</sup>.

Deletion of a 142-bp *Nsp*HI fragment in the *ARG4* promoter region decreases gene conversion within *ARG4* from 7.4% to 2% because it removes the *ARG4* initiation site (see ref. 7, Fig. 2, deletion  $\Delta$ 9). To determine if the same sequence is required for DNA breakage during meiosis, a plasmid derivative carrying the 142-bp deletion was studied in the same strain background. The two plasmids are compared in Fig. 3. The breaks at sites 1 and 3 are unaffected by the deletion and serve as internal controls. The break at site 2 however, is undetectable in the construct carrying the 142-bp deletion.

If the meiosis-specific double-strand breaks are relevant to normal meiotic recombination, they must occur on chromosomal DNA as well as on plasmid DNA. We analysed yeast chromosomal DNA in strain NKY278 in the absence of the plasmid. The breaks at sites 1 and 2 can be detected on chromosomal DNA at the same time interval after transfer to sporulation medium as is observed for plasmid DNA (compare Fig. 2b and c).

We probed the structure of the DNA termini by treating the DNA samples with S1 nuclease, which is specific for single-stranded DNA<sup>15</sup> (Fig. 4). The intensities of the fragments corresponding to breaks at sites 1, 2 and 3 remain constant after S1 nuclease treatment but, remarkably, the size of each fragment decreases. The change in fragment mobility can be seen after 2.5 min of S1 treatment and is complete at 10 min, when all these molecules have been shifted to a faster-migrating species. Prolonged S1 treatment does not result in further degradation of the fragments. The susceptibility of all the broken ends to S1

FIG. 4 Treatment of meiotic DNA samples with S1 nuclease. DNA from cells four hours into meiosis was treated with S1 nuclease in buffer containing 200 mM NaCl for the times indicated, digested with *Sph*I, and processed as in Fig. 3. The mobility of the full-length linear plasmid (25 kb) is unaffected by S1, whereas the cleaved fragments 1, 2 and 3 (19, 17 and 10 kb) show an initial rapid decrease in size, indicating that they all end in several hundred bases of single-stranded DNA.

nuclease indicates that all of these molecules terminate with a region of single-stranded DNA. The specificity of S1 nuclease means that this single-stranded region is probably degraded by the nuclease until the enzyme reaches a duplex region<sup>16</sup>. When we examined the termini corresponding to the other side of the break, we observed the same S1-sensitive profile (data not shown). Thus, both sides of each of the three breaks end with single-stranded DNA. A similar pattern of sensitivity to S1 nuclease was observed with DNA samples taken at 3, 4, or 5 h into meiosis (data not shown). The single-stranded tails are therefore seen as early as the breaks can be detected. The change in mobility of each of the fragments corresponds to a size difference of a few hundred nucleotides.

To confirm the presence of single-stranded tails on the cut molecules, we made use of the selective binding of single-stranded DNA to nitrocellulose membranes<sup>17</sup>. When restricted DNA is transferred directly from the gel without prior alkaline denaturation, fragments representing breaks at sites 1 and 2, are visible on the blot, whereas the intact fragment is absent (data not shown). Control experiments have shown that denatured, but not native, plasmid markers can be detected on these blots. Thus, non-denaturing Southern blots selectively enrich for the population of DNA molecules containing the broken ends, providing strong evidence for these molecules having single-stranded DNA at their termini.

Four arguments can be used to support the involvement of the DNA breaks we observe in the initiation of recombination. First, the DNA breaks are most abundant between three and five hours after transfer to sporulation medium, the time at which meiotic recombination occurs<sup>10,11</sup>. Second, these breaks occur at specific sites, one of which is the initiation site for meiotic gene conversion at *ARG4*<sup>7</sup>. Third, a deletion that removes the initiation site for meiotic gene conversion at *ARG4* eliminates or greatly diminishes the double-strand break at *ARG4*. Finally, both sides of each of the three breaks end in a few hundred nucleotides of single-stranded DNA. This is consistent with the invasion of duplex DNA by single-stranded DNA being a critical step in the initiation of recombination<sup>1-3</sup>.

Our data provide strong circumstantial evidence in favour of the double-strand break repair model, but do not eliminate alternative origins for the breaks. First, the double-strand breaks might be formed *in vitro* during DNA preparation. We see the double-strand breaks and their associated single-stranded tails when DNA is prepared by several different procedures, including a very rapid preparation in liquid nitrogen<sup>18</sup>. Also, S1 nuclease treatment does not increase the intensity of the fragments, as might be expected if they arose from partial breakage of a single-stranded lesion present *in vivo*. Alternatively, the breaks may arise *in vivo* as consequences of recombination. Holliday junction resolution could lead to duplexes containing nicks on both strands, or mismatch repair could proceed by double-strand gap repair<sup>19</sup>. These possibilities are unlikely because we see the breaks in homozygous diploids at the initiation site and as early as three hours into meiosis.

Assuming that the breaks we see are involved in initiation, it is likely that the single-stranded tails are involved in strand invasion, as proposed in the double-strand-break repair model for recombination<sup>2</sup>. Strand-exchange activities have recently been purified from vegetatively growing and meiotic *S. cerevisiae* cells<sup>20-21</sup>. The single-stranded DNA could therefore generate several hundred bases of heteroduplex DNA adjacent to the region of double-strand gap repair. Extensive heteroduplex DNA has been found adjacent to the ends of linear molecules in plasmid transformation systems<sup>22,23</sup>. The generation of extensive heteroduplex DNA could explain the occurrence of high levels of post-meiotic segregation for certain alleles of *ARG4*<sup>4,7,24</sup>.

Two of the break sites map within transcriptional promoters, one at the *ARG4* promoter and one between the divergently transcribed genes *DED81* and *DED82*. The third is in the vicinity of a promoter that directs transcription towards the *CEN4* region of the YCp19 vector<sup>14,25</sup>. Are these promoters identical to the recombination initiation sites? A sequence that stimulates mitotic recombination, *HOT1*<sup>26</sup>, has recently been shown to be identical to the rDNA promoter. More detailed mapping of the *ARG4* initiation site may resolve the question of the relationship between transcription and recombination initiation. □

# Countercurrent chromatography meets MS

Y.-W. Lee and R.D. Voyksner

Interfacing countercurrent chromatography with thermospray mass spectrometry provides a new analytical tool for detecting nonvolatile, hydrophilic or thermally unstable bioactive natural products.

THE development in the 1980s of modern countercurrent chromatography (CCC) instrumentation based upon the fundamental principles of liquid-liquid partition has caused a resurgence of interest in the separation sciences. The advantages of liquid-liquid extraction — the process for separating a multicomponent mixture according to its differential solubility in two immiscible solvents — have long been recognized. In spite of the limitations of the traditional countercurrent distribution methods which prevailed in the 1950s and 1960s, liquid-liquid extraction was used successfully to fractionate commercial insulin into two subfractions differing by only one amide group out of a molecular weight of 6,000 (ref. 1).

In recent years, significant improvements have been made to enhance the performance and efficiency of countercurrent methods<sup>2</sup>. The newly developed high-speed CCC technique utilizes a particular combination of coil orientation and planetary motion to produce a unique hydrodynamic phenomenon in the unilateral phase distribution of two immiscible solvents in a coiled column. The hydrodynamic properties can effectively be applied to perform a variety of countercurrent chromatographies, including true countercurrent<sup>3</sup> and foam countercurrent methods<sup>4</sup>. More recently, a 2,000 r.p.m. high-speed CCC has been developed which performs separations with speeds and resolutions comparable to those achieved using HPLC<sup>5</sup>.

We have successfully applied the high-speed CCC system in the separation of plant alkaloids, plant indole hormones, herbicides and bioactive lignins. One of the most distinct advantages offered by CCC is its lack of complications arising from solid supports, such as adsorptive sample loss, deactivation and contamination. Because the two-phase solvent system commonly used in CCC often consists of an organic phase and an aqueous phase, the technique also particularly lends itself to interfacing with mass spectrometry (MS). A solvent with a high aqueous percentage can be used with a volatile buffer such as ammonium acetate to achieve optimal conditions for thermospray MS without suffering the reduction in MS sensitivity typically observed in HPLC/MS with mobile phases low in water content<sup>6</sup>.

MS is generally regarded as the most versatile and universal detection tech-

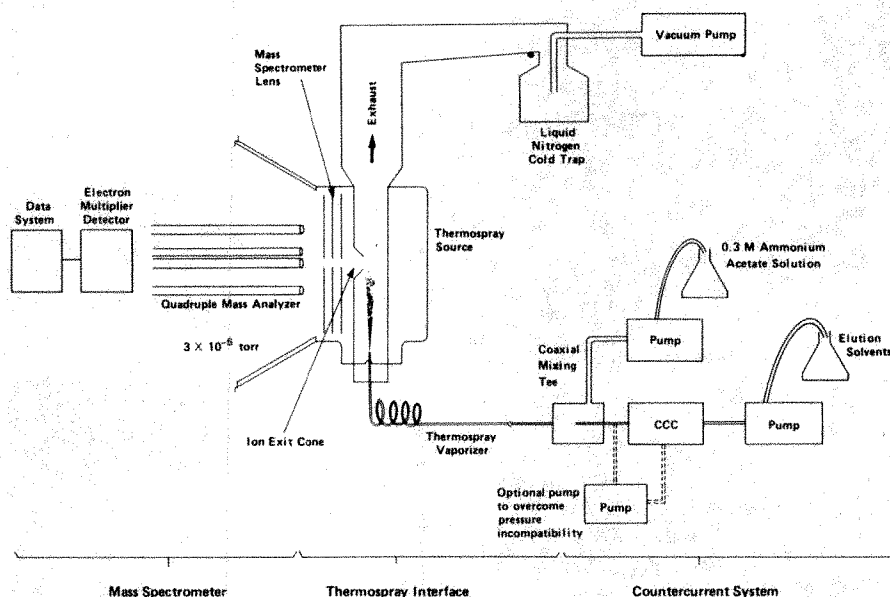

FIG. 1 Schematic diagram of the CCC/MS system.

nique for use with CCC because of its ability to detect compounds with no ultra-violet chromophore and provide precise identification of molecules. The pressure tolerance of high-speed CCC allows it to be interfaced to thermospray<sup>7</sup> mass spectrometry through an additional pump (to overcome thermospray backpressure). When the resolving power of CCC is coupled in real time with the sensitivity of MS, the individual chromatographic components need not be pure to acquire mass spectra sufficient for identification purposes. Reconstructed single-ion plots in which all of the ions of a given  $m/z$  value are plotted against retention time can be used to determine the purity of the total ion current chromatogram (TIC), where the mass spectrometer serves as a compound selective detector. If the intensity of the TIC peak does not rise and fall in accordance with the plot, it is not pure. The on-line coupling of CCC and MS also provides data on trace components which are not easily obtained when the techniques are performed separately.

## Configuration details

In our system, shown in Fig. 1, the effluent from a CCC operating at  $0.8 \text{ ml min}^{-1}$  is introduced into a pump through a zero dead volume tee fitted with a reservoir. Because the CCC produces varying flow rates, the additional pump is operated at  $0.7 \text{ ml min}^{-1}$ ; the reservoir provides extra solvent or vents excess solvent from the

CCC system as the pressure fluctuates. The effluent from the pump is mixed coaxially with  $0.3 \text{ M}$  ammonium acetate added at  $0.3 \text{ ml min}^{-1}$  to create a solvent with sufficient volatility for ion evaporation ionization<sup>8</sup>. The solvent is passed at a rate of  $1 \text{ ml min}^{-1}$  through a UV detector ( $254 \text{ nm}$ ) and into the thermospray interface. (At lower CCC flow rates of  $0.3\text{--}0.6 \text{ ml min}^{-1}$  the pressure drop across the thermospray vapourizer is sufficiently low to permit the direct coupling of the CCC effluent to the thermospray interface without the use of the additional pump.)

The thermospray interface connected to the quadrupole mass spectrometer is kept at a source temperature of  $250^\circ\text{C}$  and a vapourizer temperature of about  $170^\circ\text{C}$  to maximize the chromatography solvent cluster, which has been shown to co-maximize with the analyte under study<sup>7</sup>. No splitting of the CCC effluent is necessary. The solvent is pumped out of the source with a liquid nitrogen cold trap attached to a mechanical rough pump. The analysis is performed employing both negative and positive ion detection using ion evaporation ionization and chemical ionization.

## Early results

We have used the thermospray CCC/MS technique successfully in preliminary studies of a mixture of plant alkaloids<sup>9</sup>. Results obtained in our recent application of the technique to the study of bioactive

FIG. 2 CCC/MS ion chromatograms of the six major lignins from *Schisandra*. The chemical ionization filament in the quadrupole MS was operated at 1,000 V with a 0.15 mA emission current. The MS was scanned from  $m/z$  180 to  $m/z$  600 in 2 s. The mass calibration of the quadrupole was verified with polypropylene glycol (AMW = 1,000).

lignins<sup>10</sup> and triterpenoic acids<sup>11</sup> suggest that CCC/MS would be complementary to HPLC/MS as a useful method.

A CCC/UV chromatogram of a crude extract of the bioactive lignin from the herb *Schisandra* shows four distinct peaks. We have used thermospray CCC/MS to confirm the identification of the peaks and further to identify the minor components of the extract. The CCC/MS-selected ion chromatograms (Fig. 2) for the  $[M + H]^+$  or  $[M + NH_4]^+$  ion of the possible lignins from *Schisandra* indicated six components to be present. The major CCC/UV components present in the extract were confirmed to be schisanhenol and schisanhenol acetate based upon comparison of their thermospray spectra and retention times with the standards for these two components. The minor bioactive lignins such as schisanhenol B4 and deoxyshisandrin 6 were not sufficiently separated from schisanhenol and schisanhenol acetate by CCC with UV detection. But CCC/MS enabled the detection and acquisition of clean spectra of these trace components, which coeluted with the major components in the sample even though they exhibited different characteristic ions. The negative ion spectra for these lignins were 10 to 100 times less intense, and recorded only the major components.

The thermospray CCC/MS total ion current chromatogram presented a different picture of the relative abundances of the bioactive lignins than that obtained using CCC with UV detection. The thermospray CCC/MS response factors of the lignins are more similar than their UV extinction coefficients, enabling a more accurate estimate of the relative percentages of each lignin. Thermospray CCC/MS showed the major active lignins

## Pittsburgh preview

The Pittsburgh Conference will live up to its reputation as one of the largest scientific exhibitions when the doors open in Atlanta, Georgia next week on new products from over 800 companies.

ZYMARK Corporation offers specially configured laboratory robotic systems for automated titrations (Reader Service No. 101). Using Zymark's PyTechnology hardware, the robotic systems can handle the preparation of liquids, viscous liquids and solid samples for Karl Fischer and general titrations. The samples are prepared by the robot, in a sequence that is specified by the operator, and placed directly into the titration cell. The robot starts the titration and monitors all operations to ensure a proper titration. When the titration is done, the results are sent

Zymark's new System V robot controller, for data management and report writing.

back to the robot and a report is generated. Zymark says the robot yields more accurate and precise data than that collected from manual experiments, because its operations are truly reproducible. The company's new System V robot controller performs data management and report writing functions, and archives and transmits data to central computers.

Karl Fischer and general titrations can now be done automatically with Zymark's robot.

from *Schisandra* to be schisanhenol (54 per cent), pregomisin (21 per cent), meso-dihydroguaiaretic acid (13 per cent) and schisanhenol acetate (10 per cent). A total of six lignins were identified: the remaining molecules were nonpolar components with high partition efficiencies in the stationary phase that were not eluted at the same time under the mobile phase conditions.

The coupling of CCC to MS is in its early stages, and new refinements are continually being made. Thick-walled tubing and connections that withstand the high backpressure (roughly 600 p.s.i.) of thermospray MS will make CCC/MS more convenient and easy to use. An analytical CCC system capable of operating at 4,000 r.p.m is being developed in the Laboratory of Technical Development at the US National Institutes of Health which should raise the separation capabilities of the technique. The feasibility of using two aqueous non-immiscible

International Scientific Instruments is announcing its new computerized scanning electron microscope — the model SX-40A (Reader Service No. 102). The microscope's evacuation system, high-voltage turn-on function and emission settings are all automated for one-touch operation in sequence. The SX-40A's special features include a motor-driven specimen stage, computer-aided auto-focus and auto-stigmator, and automatic contrast/brightness control. The system operates a

solvent systems for separation of proteins is also being investigated. □

Yue-Wei Lee and Robert D. Voyksner are at the Chemistry and Life Sciences Division, and the Analytical and Chemical Sciences Division, Research Triangle Institute, Research Triangle Park, North Carolina 27709, USA. For more information, fill in reader service number 100.

ISI's computerized SEM is designed for operation at the touch of a single button.

accelerating voltages from 1 kV to 30 kV, allowing it to be used in both beam-sensitive applications and at high beam energies with an ultimate resolution of six nanometers. Samples of up to six inches in diameter can be examined, with scanning speeds variable from 0.2 to 160 seconds. A full selection of options allows the \$45,000 (US) system to be tailored to specific user requirements and applications.

Sartorius Instruments will introduce its new **PLUS performance package for balances** at the Pittsburgh Conference (Reader Service No. 103). The instrument has a microprocessor-based keypad with a menu of 16 useful functions that expedite common weighing applications. A few of the functions include the storage of identification numbers, calculation of the

Sartorius's PLUS package gives its range of balances a host of special functions.

weight of residue in per cent, a fill-toward-zero capability, and even live animal weighing.

Oriel Scientific Ltd has a new catalogue on **lasers and accessories** which contains a valuable composite of new and existing products, with support to build up applied systems (Reader Service No. 104). Included are both solid state and conventional HeNe lasers, with full details of supporting optics, launching devices, beam splitters, expanders, mirrors, etalons, optical filters, fibre optics and attenuators. Oriel has pitched the free 80-page catalogue to be useful to both research scientists and applied engineers.

### The UV/visible scene

Varian has a new **software interface** program for coupling its Cary 200 series of UV/visible near-IR spectrophotometers

with IBM PC's (Reader Service No. 105). The \$1,250 (US) PC Control program provides centralized control of the spectrophotometer from an IBM PC/AT or PS/2 model 30 or 50. Key features of the package include the ability to store and retrieve instrument parameters, display data in real time, produce multicolor pen plots, and convert data to standard formats usable by other IBM-compatible

A screen display from Varian's software interface for its UV/visible near-IR spectrophotometers.

software packages. PC Control has a graphical interface which allows the user to scroll through display options, confirm selections, and move step-by-step through the software.

Perkin-Elmer's **Lambda 6 PC-controlled UV/visible spectrophotometer** was designed for applications in environmental, pharmaceutical and biochemical analyses (Reader Service No. 106). The Lambda 6 PC system is comprised of the double-beam, scanning Lambda UV/visible spectrophotometer integrated with an industrial-standard personal computer and software. Perkin-Elmer says the optical design of the system ensures low stray light, spectral fidelity, fast scan speeds, baseline stability and low noise. The system's software automatically processes and stores data from procedures such as scanning, time drive, wavelength programming, spectral processing and kinetics studies. Its open-ended design allows future expansion to increase data handling capabilities.

Perkin-Elmer's Lambda 6 UV/visible spectrophotometer is controlled by a computer.

Secomam is introducing a **computer-driven spectrophotometer** at the Pittsburgh Conference, designed to scan the entire UV/visible range at speeds of up to 2,400 nm per minute (Reader Service No. 107). In addition to standard measurement modes, Secomam's model S.1000 can perform kinetic measurements at a single wavelength with sampling rates of as high as 30 per second. The system's software can carry out sophisticated calculations — including derivatives up to the fourth order — curve storage, and curve expansion. Up to five components of a single solution can be quantitatively analysed automatically with the system. A multi-standard calibration function permits four different curve fitting models and as many as twelve different combinations of math-

Secomam's S.1000 spectrophotometer also comes with a microprocessor instrument.

ematical axes. The cell compartment can accommodate cells with light paths up to 100mm long, for highly sensitive detection of low level components.

New **quantitative analysis and enzyme kinetics software** is now available from Hewlett-Packard for its model HP 8452A diode array UV/visible spectrophotometer and ChemStation (Reader Service No. 108). The HP 89511A quantitation software package simplifies single component method development and multicomponent analyses. In single component analyses, the software allows the selection of

wavelengths which provide the best calibration curve and the greatest reproducibility. The concentrations of up to twelve components can be determined within a known sample matrix. The software allows the use of absorption and derivative spectra, and the company says it saves time in method development by mathematically synthesizing spectra before measuring actual samples to determine the feasibility of performing the multicomponent analysis. The new enzyme kinetics package, model HP89512A, provides biochemists with the means to investigate enzyme reactions, rate data and reaction models. Nine mathematical models are available, or users can develop models from their own equations. The kinetics of several reactions may be measured in parallel with the help of a new multi-cell transport mechanism for the HP spectrophotometer.

## Capillary electrophoresis

Bio-Rad is now offering an instrument for performing **high performance capillary electrophoresis** (*Reader Service No. 109*). The new model HPE 100 system can perform high-resolution separation and analysis of a variety of samples, including peptides, proteins, DNA fragments, amino acids, bacteria and viruses. The

Bio-Rad's benchtop unit for performing capillary electrophoresis.

system is a compact benchtop unit which contains an electrophoresis chamber and all of the electronics in a safe interlocked cabinet. Separation takes place in a short, narrow-bore capillary tube with a patented coating which Bio-Rad says eliminates electroendosmosis. Samples are injected with a microliter syringe and the electropherogram results are produced on either a strip chart recorder, an integrator, or a PC-driven data collector within about ten minutes, according to the company. Electrophoresis methods that can be adapted to HPE include free zone, displacement and discontinuous methods, and isoelectric focusing.

Applied Biosystems is also introducing a new system for **high-pressure capillary electrophoresis** — its new model 230A

Applied Biosystems's entry onto the capillary electrophoresis market.

HPEC system (*Reader Service No. 110*). The capillary electrophoresis process enables the user to separate, visualize, quantitate and recover mixtures of biological macromolecules. The 230A HPEC is a micro-preparative instrument for the separation and purification of proteins, DNA, and synthetic oligonucleotides. Applied Biosystems says the system offers the resolving power of gel electrophoresis with the convenience of continuous sample elution, real-time visualization and direct sample collection. In addition, HPEC collects peaks of interest for further analysis or purification. As samples are eluted from the tube gel, a continuous flow of elution buffer carries the separated sample components through an on-line detector and into an integral fraction collector. The temperature-controlled gel compartment accepts a variety of column diameters and lengths, and the programmable power supply offers multiple operation modes. The company says standard electrophoresis protocols may be adapted readily to the tube gel format of the system.

## Chromatography currents

Sanki Laboratories has a new model LLB benchtop, high-speed **analytical centrifugal partition chromatograph** (*Reader Service No. 111*). Centrifugal partition chromatography (CPC) is a new liquid chromatographic technique which utilizes liquid-liquid partition and countercurrent distribution to fractionate complex mixtures of chemical substances. Because CPC is not based on a solid stationary support, there is no pH limitation, irreversible retention or catalytic molecular

Sanki's newest analytical centrifugal partition chromatograph runs at 2,000 r.p.m.

rearrangement of labile species. The model LLB's main centrifugal module can be operated at speeds of up to 2,000 r.p.m. The unit contains 8,000 partition channels for the high-efficiency analysis of mixtures ranging from natural products and pharmaceuticals, to antibodies and genetically engineered products.

Dionex has announced what may be the first system for **environmental analysis** to bring together the power of HPLC, ion chromatography and flow injection analysis (*Reader Service No. 112*). The basic system consists of a quaternary gradient module, a chromatography module and a postcolumn module. A column-switching valve allows a single sample to be analysed using various combinations of variable wavelength detectors, fluorescence detectors, a conductivity detector and a pulsed amperometric detector. Post-column derivatization adds the ability to determine contaminant amounts down to p.p.b. levels. The system can be quickly adapted for flow injection analysis by replacing the chromatographic column with a method-specific AppliCard. The fluid path in all of the system components is metal-free, so all types of solvents can be used without corrosion concerns.

A new **capillary SFC method development kit** is now available from Lee Scientific (*Reader Service No. 113*). The kit contains four 2.5-m, 50  $\mu$ m i.d. columns containing one of each of the following four phases: SB-Octyl-50, SB-Biphenyl-30, SB-Cyanopropyl-50 and SB-Smectic-50. Lee says the 2.5-m columns produce quick results during screening runs, yet deliver efficiencies high enough for the resolution of complex samples, so that they may be rapidly screened to determine which stationary phase is best suited for a particular application.

Perkin-Elmer has a new **liquid chromatography system** which offers computer control for methods development and automated sample processing (*Reader Service No. 114*). The Perkin-Elmer LC Analyst system includes a quaternary LC pump, random-access autosampler, and a personal computer with LC Analyst software. It will accept data from any detector, and is designed to assist chromatographers in the development of methods even when little or no sample information is available. Perkin-Elmer says the LC Analyst's ability to process large numbers of samples automatically and thorough documentation allow developed methods to be transferred easily to routine use.

Special features of the LC Analyst system include customized methods development, software packages, history file reports for the documentation of methods and real-time changes, and automatic systems startup and shutdown.

The Waters chromatography division of Millipore has designed a Peptide Analyzer for high resolution **peptide mapping** (*Reader Service No. 115*). The HPLC system features dual flow paths optimized

Waters' system for use in peptide mapping.

for microbore and analytical scale operation. The analyzer comes with the Power-Line HPLC controller, which allows single-point control of gradient, injection and detection parameters. The system is also equipped with the Waters model 990+ Photodiode Array Detector which offers complete UV/visible spectral analysis. Spectra can be directly compared to those acquired previously using the detector spectral library. Waters says the system is ideal for the preparation of picomole amounts of pure peptides for sequence determination, peptide maps for the quality control of recombinant DNA products, or for qualitative structural analysis.

### Analytical spectroscopy

Spectra Tech has redesigned its FT-IR Spectra-Scope to allow the **microsample analysis** of crystals, fibres, laminates, con-

Spectra Tech's 'scope has been redesigned for microsample analysis.

taminants, and other small samples difficult to load onto a standard beam condenser (*Reader Service No. 116*). The scope has a 15 $\times$  collecting objective and a 10 $\times$  ocular lens which together magnify the sample area up to 150 times. The company says the Spectra-Scope has a low signal-to-

noise ratio, even with a sample as small as 15  $\mu$ m. Samples are positioned using the X-Y-Z translation stage and light straying is minimized with a remote aperture which masks the image of the sample. Illumination is provided by a high intensity lamp with intensity adjustment. The new \$8,500 (US) Spectra-Scope is designed for use with most FT-IR spectrometers.

Applied Research Laboratories is launching a new version of its thermally stabilized SpectraSpan VII **multi-element spectrometer**, available in either simultaneous or sequential configuration (*Reader Service No. 117*). In simultaneous mode, ARL says the SpectraSpan VII is capable of determining as many as 20 elements in 30 seconds; sequentially, it can determine more than 70. The computerized, bench-top spectrometer is controlled by an IBM PS/2 computer and MS-DOS software that provides operator feedback, generates internal reports, and documents all analytical diagnostic information. The spectrometer features automatic dynamic background correction and high resolution, and a new digital LCD display for gas flow control and profiling functions. The SpectraSpan VII can be used in environmental, clinical, agricultural and geological laboratories.

Philips is introducing its model PW1480 **sequential X-ray spectrometer** — a versatile system for applications requiring high performance and flexibility in the analysis of solids, powders and liquids (*Reader Service No. 118*). Developed from the PW1400 series, a new model incorporates a number of proven features: a high precision goniometer, a 60 kV or 100 kV generator, and a wide range of single- and dual-anode X-ray tubes. With the model PW1480, Philips has added a wider choice of collimator and crystal options, plus a bidirectional, eight-position crystal changer to facilitate custom tailoring. To go with the spectrometer, Philips offers its new X-40

analytical software package, which has facilities for both quantitative and qualitative spectrometer operation, and a user interface which supports both the command and menu modes. To make the software easier to use, Philips has included logical defaults at input points throughout the program and easily accessible "help" information. Philips says the software package reduces calculation time by allowing automatic qualitative and semiquantitative analysis of several samples with a single command.

Jeol has a new **mass spectrometer with ion optics** which it says is as equally suited for high-sensitivity, high-resolution GC/MS as it is for high-molecular weight

Ion optics of Japanese design enhance Jeol's new mass spectrometer, the model SX-102.

LC/MS measurements (*Reader Service No. 119*). The Jeol SX-102 can be used to detect very small traces of drugs, pesticides and pollutants with the SIM GC/MS technique. Its LC/MS applications using the frit inlet system include the analysis of amino acids, peptides, proteins and pharmaceuticals. The instrument's QHQ optics geometry, created by Matsuda of the University of Osaka in Japan, provides high ion transmission and positively shapes the beam to allow a slit width five times that of conventional mass spectrometers, for high sensitivities at both low and high resolution. The instrument has a practical mass range of 3,000 daltons at 8 kV, but Jeol says it can measure compounds of greater than 5,000 daltons, such as bovine insulin.

Philips' sequential X-ray spectrometer can handle solids, powders and liquids.

Analyte's answer for multielement atomic absorption spectrophotometry.

Analyte Corporation is introducing its new model SL-16 **multielement atomic absorption spectrophotometer**, which the company says is capable of determining in rapid sequence the concentrations of up to 20 elements in either liquid or solid samples (*Reader Service No. 120*). The SL-16 contains a fast-moving turret which holds 16 hollow cathode lamps combined with a monochromator programmed to move to the correct wavelength while the turret is rotating. Analyte claims the system can determine 20 elements from one sample in under two minutes. Conventional burner systems can be used with the spectrophotometer for liquid samples; Analyte's Atomsource glow-discharge device is required to atomize solid samples into the argon gas stream. The Atomsource can be connected to the spectrophotometer in roughly 10 minutes. The SL-16 is controlled by an AT-type computer that can be programmed with up to 400 different analytical methods, each of which includes lists of elements, wavelengths, and slit widths.

### Information resources

Savant's 1989 catalogue of audiovisuals for **chemical laboratory training** contains 76 programmes covering a variety of

Savant's catalogue on tutorials.

analytical techniques for both industrial and medical applications (*Reader Service No. 121*). Available training programmes range from peptide analysis and UV/visible spectroscopy, to general laboratory procedures and chemical safety. Most Savant programmes are available as both slide and cassette tape shows and videotapes in Beta or VHS formats. The programmes are professionally narrated, and vary in length from 20 to 45 minutes.

The Sigma-Aldrich Company has published the second edition of its two-volume library on **chemical safety** (*Reader Service*

Sigma-Aldrich's volumes contain things chemists need to know for a safer lab.

*No. 122*). Over 14,000 chemicals and 24,000 products are listed in the two books, with information ranging from chemical structure and physical properties to health hazards and recommended waste disposal methods. The volumes together contain 4,098 pages, and cost \$325 (US).

Finnigan MAT is offering a free **colour wallchart** to be used in the interpretation of peptide and protein mass spectra (*Reader Service No. 123*). The information provided on the wallchart includes amino acid structures, molecular weights, and hydrophobicity indexes. The wallchart also lists the gas phase fragmentation pathways of peptide chains and the differences between their nominal, average and exact molecular weights. The colour wallchart is the first of a series

planned by Finnigan MAT to explain the biochemical applications of mass spectrometry; the company will introduce additional wallcharts later this year.

To complement its "How To" notes detailing applications and techniques for using FTIR spectrometers, Mattson

Mattson's FT-IR spectroscopy videotape.

Instruments Ltd is releasing an **education film** entitled "Infra-Red Spectroscopy" (*Reader Service No. 124*). The video-cassette film is produced in conjunction with the British Broadcasting Company's Open University programme, and offers both the established and the potential user theoretical and practical information on the FTIR spectroscopy technique. A range of methods for the measurement of gas, solid and liquid samples are demonstrated on the video, using Mattson FTIR spectrometers.

The 1989 **catalogue** is now available on the Eyela line of scientific instruments from Tokyo Rikakikai Company Ltd. (*Reader Service No. 125*). The 45-page catalogue lists a host of products for analytical chemistry, cell culture, microbiology, and biotechnology. Besides such basic laboratory items as freeze-dryers, water baths, incubators, ovens and water purifiers, the Eyela catalogue spells out Tokyo Rikakikai's specialty systems for laboratory- or production-scale rotary evaporation, cell immobilization and carboxylic acid analysis. The catalogue also describes the company's line of batch and airlift bioreactors for plant and animal cells, and fermentation pilot plants. For chromatography needs, the catalogue includes information on the Eyela droplet counter-current chromatograph, flash chromatograph, rotation locular counter-current chromatograph and liquid-liquid counter-current extractor.

Beckman is introducing its new **Data Logger software for spectrophotometry** at the Pittsburgh Conference, and is exhibiting the package along with one of its DU Series 60 spectrophotometers (*Reader Service No. 126*). Data Logger allows users to log discrete absorbance readings of up to 114 samples on 3.5-inch diskettes, collect wavelength scans, carry data to

Beckman's new Data Logger software expands the capabilities of its spectrophotometers.

another IBM PC or PS/2 personal computer for analysis, and convert data to Lotus format. With the software, users can add or subtract spectra, and display up to six spectra on the screen for direct viewing and comparison. The Data Logger package includes an IBM PS/2 model 25 computer with 640 kBytes RAM and dual 3.5-inch disk drives, DOS version 3.3, the Beckman DU Data Capture software program, a formatted data diskette and necessary cables. Data Logger also supports the Beckman DU-50 and DU-70 series spectrophotometers, and the DU-6 and DU-7 UV-visible spectrophotometers.

### Biology at Pittcon

OROS Systems, Inc. is launching its second instrument for **protein purification** — the touch-screen operated MultiLab system (*Reader Service No. 127*). OROS designed the MultiLab for use in small-scale preparative purifications and for determining optimal purification methods. The operator chooses the preferred method by touching the MultiLab's touch-sensitive screen, and the expert software system takes over to monitor the purification and control all parameters. The \$35,000 (US) MultiLab runs at both low and medium pressures, and includes air sensors to detect the absence of buffers and an air eliminator to protect the column. OROS Systems says the system can be used with immunopurification, affinity chromatography, hydrophobic interaction chromatography, ion-exchange, gel-filtration or chromatofocusing techniques.

The Generator **DNA synthesizer** will be on display in DuPont's booth at the Pittcon show (*Reader Service No. 128*). The \$22,500 (US) Generator uses  $\beta$ -cyanoethylisopropyl phosphoramidites, which DuPont says demonstrate consistently high base-to-base coupling efficiencies. The precision fluid meter of the Generator delivers microlitre quantities of reagent to the reaction column to save reagents, and can perform at least 100 coupling cycles before requiring replenishment, according to the company. The Generator has a built-in system check which alerts the user and places itself on hold if either fluid flow or gas pressure fall outside set parameters. Operating the system requires no computer language

skills: nucleotide sequences are entered directly from the keyboard, and the screen display shows the status of the reaction cycle and the base position in the sequence. A custom programming function allows users to develop their own chemistry programs, which can be stored on disk through the system's floppy disk drive. DuPont offers a complete range of pre-measured reagents for use with the Generator which come in thumb-screw-on bottles that cannot be misinstalled.

Polymer Laboratories Ltd have a new line of **LC columns** for protein analyses which link the company's biocompatible metal-free column with a range of quaternized PL-SAX strong anion exchange materials (*Reader Service No. 129*). The PL-SAX media are composed of a quaternary amine applied to a rigid macroporous polymer, giving a pH range of 1–13 and a high degree of physical stability.

Molecular Devices recently introduced the first laboratory instrument to employ biosensor technology — the **Threshold total DNA assay** system based on the light-addressable potentiometric silicon sensor developed by Hafeman, Parce and McConnell (*Reader Service No. 130*). The Threshold system quantitates contaminating DNA in samples of biotechnology products, down to the picogram level. In the first step, the sample is incubated for one hour with a single reagent that contains two binding protein conjugates: a single-stranded binding protein linked to a hapten specific for the capture membrane, and an anti-DNA monoclonal antibody joined to urease. The sample is then transferred to the vacuum unit of the Threshold, which concentrates it onto eight measurement sites on the Threshold biosensor

Polymer Lab's all-glass setup for the chromatography of biomolecules.

stick. When the stick is dipped into the reader, it comes in contact with urea, and the ensuing enzyme reaction changes the local pH at each measurement site, which alters the surface potential of the sensor proportionally to the amount of DNA present. Molecular Devices says all DNA fragments larger than 100 bases can be quantitated with the computer-driven Threshold system, which can process up to 32 samples in roughly 15 minutes. The company is currently developing other DNA probe and immunoassay kits for use with the Threshold.

### Japanese Imports

Asahi Chemical sells a **desk-top desalinator** called the Micro Acilyzer based on electrodialysis with an ion-exchange membrane (*Reader Service No. 131*). The electrodialysis technique employs a pair of cation- and anion-exchange membranes which are activated by an electric potential to transport negatively and positively charged ions out of the sample. Asahi says its Micro Acilyzer can be used for the desalination of oligosaccharides, and the removal of phosphate buffer from peptides and nucleosides. The company sells two versions of the Micro Acilyzer: model G1 processes 10 ml samples, and model G3 can desalinate up to 1,000 ml.

The model SDM5500 **dynamic mechanical spectrometer** from Seiko Instruments can be used for the measurement of the physical properties of solid materials (*Reader Service No. 132*). The instrument consists of a rheometer, an analysis module and an X-Y plotter. Stress from the force generator is applied by a probe, and the strain caused in the sample is measured as the displacement signal by a strain meter, and sent to the computer for processing. The system's software incorporates windows so that running conditions and data can be viewed simultaneously. □

### ADVERTISEMENTS

**LIPOSOMES**

REPRODUCIBLE — HOMOGENEOUS —  
EXTREMELY RAPID

Our new LIPOSOMAT guarantees rapid (5ml within 60 minutes) preparation of uniformly sized unilamellar liposomes. Liposome size is selectable between 25 and ca. 600 nm diameter. Sample volume is normally 5–10ml or up to 200ml if used in combination with an additional instrument. Lipid concentration can be up to 300 mg/ml.

Reader Service No.45

# Move the work or move the people?

Richard Pearson

Pressures on the crowded and expensive south-east corner of England are leading to 'satellite offices' and long-distance commuting. Many companies see relocation as the only answer.

DESPITE a fast-growing economy, great regional disparities remain in the United Kingdom. In many of the inner cities and towns in the North, unemployment remains stubbornly high, often reaching levels in excess of 15 per cent. Yet in many parts of the South-East, registered unemployment has fallen to under 5 per cent and skill shortages are growing worse. In an effort to alleviate the worst effects of these shortages employers are now looking to recruit from farther afield, in some cases extending their catchment areas by a few miles, in others encouraging long-distance commuting from several hundred miles away. Others are setting up remote networking centres while others are relocating in order to find the staff they need.

A recent study of the South-East has shown the different stages of distance recruitment clearly<sup>1</sup>. The sizes of the individual local catchment areas vary greatly, increasing with the seniority of the appointment, the nearness to the centre of London, and to a lesser extent transport links. The better the links the greater the distances people are prepared to travel.

## Perks?

The first response of employers to shortages is to consider applications from beyond the usual spatial area. This usually involves advertising in the local media, and is a fast, easy, low-cost option. Companies are often reluctant to make even this simple move, fearing poor time keeping and increased absenteeism as a result of long-distance travel. In London, 64 per cent of the professional staff surveyed spend more than an hour travelling to work, compared to 7 per cent in the rest of the South-East and even fewer in some other parts of the country (see table). Towns such as Bristol, Coventry, Doncaster and Ipswich, are now joining the South-Coast resorts such as Brighton and Eastbourne as regular commuter towns for London. Surprisingly, outside of the construction industry, few firms offer improved financial or other assistance with commuting costs such as season ticket loans or car purchase schemes. These are still seen as perks rather than as recruitment aids.

The next step for recruiters is rather bigger and involves advertising in more distant labour markets. Here, a major problem is choosing which labour market might be appropriate, the main indicators used being the prevailing level of local unemployment, local employment struc-

ture and reports of redundancies in firms similar to their own. Firms with branch networks, however, are able to use them as information sources and recruitment agents, and also encourage staff transfers into the South-East. High-tech firms tend to use consultants.

## House prices

There remains, however, a growing reluctance on the part of individuals to move into London and the South-East, with regional house price differentials being a major barrier<sup>2</sup>. In contrast with their reluctance to improve the assistance for longer distance commuting, most firms surveyed are improving their relocation package, although only a minority are investing in sheltered housing, and assisting in property disposal and search, property leasing schemes and joint equity schemes. The numbers of staff benefiting from the latter are small. For most companies the response is financial, providing reimbursement for the costs involved in the move as well as for higher costs in the new area, and supplements to compensate for the disruption. Few companies have detailed knowledge of the real costs involved, but their estimates of expenditure were in the range £5,000-£10,000 with a tax exemption

opportunities. About half of them were employed on temporary or short-term contracts, few were allowed to adjust their working patterns to fit in with their travel arrangements. The extra costs of this travelling tend to fall on the individual, with little subsidy or inducement coming from the employers<sup>3</sup>.

Another variation on long-distance working that is now being pioneered in the United Kingdom is that of network information technology centres in inner cities, remotely serving customers in the South-East. Recruitment to these centres is likely to be from local training schemes and it is intended that the centres will not only be commercially viable, but will also provide valuable work experience and further training to those who would be otherwise employed, and boost the skills profile of the local community. The technology is already proven, the key is to attract the customers. In the United States a number of companies now send all their low-level data processing work via satellites to centres in the Caribbean where wage rates are way below those of the United States — in some cases below even the cost of office rental in North America.

An increasing number of employers, including central government, are also

Travel-to-work times in selected regions

Journey time	London	South-East	North	Wales
0-29 min	7%	62%	57%	72%
30-59 min	29%	30%	36%	26%
60+ min	64%	7%	7%	2%

Data from ref. 1

limit of £8,000 last year. (Tax exemption is now being increased to £17,200.)

Although many of the available jobs are in the South-East, financial, housing and social reasons often mitigate against a move to the region. Now there is a growing class of professional long-distance commuters, with as many as 10,000 people regularly travelling from the North to work in London and the South-East. Interviews with a small sample of these commuters show that many are middle managers continuing in jobs or careers that they had had earlier in their lives, but that they are now earning far higher salaries than they were previously and demand high levels of job satisfaction. A major motivation for many 'long-distance commuters' interviewed was a history of redundancy, not that of long-term unemployment, and the lack of local job

moving the whole workplace and setting up offices outside the South-East to capitalize on their property assets, at the same time alleviating skill shortages. With labour supply and working conditions unlikely to improve in the South East in the foreseeable future, relocation of the work, whether in terms of the whole office or just part of the workload via telecoms links, looks like a more effective long-term solution than trying to attract more people to travel or move to the work. □

### THE UNIVERSITY OF CHICAGO

#### Department of Biochemistry & Molecular Biology **POSTDOCTORAL FELLOW POSITION, STRUCTURE AND FUNCTION OF RAS PROTEIN**

A position is available to study biochemistry of ras proteins. (1) C-terminal modification and membrane association of ras and other CAAX box containing proteins. The study will utilize yeast system and will focus on palmitoylation, carboxymethylation, proteolytic cleavage and farnesylation. (2) Guanine nucleotide binding and GTPase activation of ras proteins and their interaction with GAP.

Send curriculum vitae or call 312-702-1339, **Dr. Fuyu Tamanoi, Department of Biochemistry and Molecular Biology, The University of Chicago, 920 E. 58th St., Chicago, IL. 60637.** (NW3389)A

### Postdoctoral positions

available immediately for Biochemists, Biophysicists and Molecular Biologists to study (1) The Mechanism and Regulation of Gene Expression in both Prokaryotic and Eukaryotic Systems, and (2) the Nucleic Acid-Protein Interactions. Send resume and three letters of recommendation to **Professor Cheng-Wen Wu, Dept. of Pharmacological Sciences, SUNY Stony Brook, Stony Brook, NY 11794-8651.** SUNY Stony Brook is an affirmative action equal opportunity educator and employer. AK 32. (NW3380)A

### UNIVERSITY OF BRISTOL

Faculty of Engineering

#### **Lectureships in Computer Science**

Two posts are available: one appointment will be made in the area of logic programming and artificial intelligence (ref. JPB25) and the other in the general area of parallel computation (ref. JPB26).

Parallel computation, which includes the design and implementation of parallel computing systems and also their applications, is seen as an area of major importance and, within the Faculty, there are groups addressing both fundamental design problems, especially for logic programming systems, and also specific application areas, in particular computer vision. The successful candidate will be expected to join one of these groups.

For the post in logic programming, applications are invited from candidates whose research interests would strengthen existing research activity in logic programming, which includes language design, knowledge base systems, theory of logic programming and natural language processing.

Starting salary in the range £9,260-£14,500 per annum.

For further details telephone Bristol 303136 (ansaphone after 5pm) or write to the **Personnel Office, Senate House, Bristol BS8 1TH.** Please quote the reference of the post which interests you.

Closing date 20 March 1989.

(8565)A

## **Asthma Research in Sandoz, Basel/Switzerland**

The asthma research programme at Sandoz seeks to relate clinical pharmacology and clinical experience of anti-asthma drugs to pharmacology of laboratory mammals when subjected to acute provocation stimuli (allergen, cytokines, PAF or pharmaceuticals) or to chronic exposure (asthmagenic chemicals, PAF, allergens or infectious agents). Measurements of pulmonary function, eosinophil accumulation, mucociliary clearance and novel tests involving platelet activation are used for drug evaluation. Considerable emphasis has been given to electronic capture and processing of data, so that work stations are integrated as a local network and will be linked to complementary laboratories within Switzerland, USA and Japan. A primate laboratory equipped to clinical intensive care standards has been established in order to relate preclinical research to clinical pharmacology and a long-term collaborative relationship has been initiated with a clinical research group specialising in asthma, based in the Swiss Institute of Allergy and Asthma Research in Davos.

Expansion of the asthma research programme in Sandoz necessitates appointment of three post-doctoral scientists to join the preclinical asthma research group.

Applicants (aged less than 35) will be expected to direct research projects and hence should have undertaken a period of independent post-doctoral research.

**PHARMACOLOGIST** to investigate airway hyperreactivity. A background in pulmonary or platelet pharmacology or physiology would be appropriate.

**PHARMACOLOGIST** to investigate the mechanism of eosinophil accumulation and activation with particular emphasis upon the interaction between interleukins and PAF in such processes.

**BIOCHEMIST** to establish molecular mechanisms that could explain efficacy of novel anti-asthma compounds with both prophylactic and bronchodilator efficacy. Close collaboration with chemists and pharmacologists and a willingness to consider a wide range of biochemical options will be necessary to fulfill the promise of this new post

Applications including curriculum vitae should be sent to:

**Sandoz Ltd., Personnel Department, ref 9801,  
 attention Mr R. Zbinden,  
 CH-4002 Basle, Switzerland**

## Royal Postgraduate Medical School

(University of London)

### MRC/LRF LEUKAEMIA UNIT

## MRC Scientist Molecular Basis of Leukaemia

Applications are invited from suitably qualified candidates to lead a molecular biology group within the Unit. Applicants should have a strong background in any area of molecular or cell biology and a desire to understand leukaemogenesis and the pathophysiology of leukaemia cells.

The MRC/LRF Leukaemia Unit has recently been expanded and its scope developed to include investigations into the molecular basis of leukaemia.

The Unit includes the LRF Centre for Adult Leukaemia and is closely integrated with the clinical service and the laboratory of molecular genetics in the Department of Haematology, within which the Unit is located.

The successful candidate will be offered a fixed-term or career appointment according to qualification and experience, with remuneration at an appropriate point for University non-clinical scientific staff.

Postdoctoral positions may also be available.

Informal enquiries may be made to the Unit Director, Professor L Luzzatto, on 01-740 3234.

Candidates are invited to apply with a curriculum vitae, names of three referees and a statement of research plans to the **Personnel Office, Royal Postgraduate Medical School, 150 Du Cane Road, London W12 0NN (01-740 3204)**, quoting ref: MB/LRF.

Closing date: (1 month).

(8559)A

## UNIVERSITY OF BRISTOL Lectureship in Physics

Applications are invited for the post of Lecturer in Physics. It is hoped to appoint an experimentalist with interest and experience in the physics of liquids and amorphous solids.

The appointment will be on the salary scale for Lecturers, currently £9,260–£19,310 per annum.

Applications should be made by letter stating special academic and research interests and should include the names and addresses of three referees, and should be accompanied by a full curriculum vitae. Applications should be sent, quoting reference JPB/36, by 23 March 1989 to the **Registrar, University of Bristol, Senate House, Bristol BS8 1TH** from whom further particulars about the post and the research work at present in progress may be obtained.

(8552)A

## ROYAL POSTGRADUATE MEDICAL SCHOOL (University of London)

### DEPARTMENT OF CHEMICAL PATHOLOGY A Grade 1A Post-Doctoral Scientist

is required for a 3 year MRC-funded project grant to write a novel cell-surface molecules involved in the adhesion of T lymphocytes to various targets. Experience in monoclonal antibody technology and T cell clone biology would be valuable.

Salary range £13000–£16000 (inclusive of London weighting).

For further information contact: Dr M W Makgoba  
01-743 2030 ext. 2118.

Proposed starting date: mid April 1989.

Application forms and further particulars available from the **Personnel Office, Royal Postgraduate Medical School, 150 Ducane Road, London W12 0NN** (tel: 01-740 3204) quoting ref: AC/MRC.

Closing Date: 16th March 1989.

(8589)A

## SCOTTISH CROP RESEARCH INSTITUTE Invergowrie, Dundee DD2 5DA RE-ADVERTISEMENT

### HIGHER SCIENTIFIC OFFICER (BAND I) POTATO AND BRASSICA GENETICS DEPARTMENT

A vacancy exists for an HSO within the Potato and Brassica Genetics Department of SCRI. The Department is responsible for the largest state supported potato genetic research programme in the UK.

The appointee will join a multidisciplinary team working in all aspects of the genetics of the potato. He or she will be expected to initiate research into the use of true (botanic) seed of the potato as part of a new strategic initiative in this area and collaborate with colleagues in other ongoing programmes.

Salary: £9,219–£12,505

Non-contributory superannuation.

Qualifications: First or upper second class honours degree with at least two years post-qualifying relevant research experience which may be a course of research and study leading to a Ph.D. degree.

The Institute is an equal opportunities employer.

Curriculum vitae complete with the names and addresses of three referees should be sent to **Mr I Paxton, Personnel Officer**, by 17th March, 1989, quoting the appropriate reference PBG/88/4/N (8574)A

## ROOSEVELT UNIVERSITY DEPARTMENT OF BIOLOGY FACULTY POSITIONS IN GENETICS AND VERTEBRATE BIOLOGY

The Department of Biology, Roosevelt University invites applications for two assistant professor, tenure-track positions. Exceptionally well-qualified candidates may be considered for appointment at the associate professor level. Applicants for the genetics position should be able to offer an introductory genetics course and advanced undergraduate and graduate course work in their speciality. The ability to offer a graduate biostatistics course would be valuable. Applicants for the vertebrate biology position should be able to offer a vertebrate biology course and advanced undergraduate and graduate courses in their speciality. The ability to offer an undergraduate developmental biology course would be valuable. Both positions also entail offering portions of the departmental core courses.

Roosevelt University is a small, privately-funded, urban university located in downtown Chicago and at two suburban locations. Applicants should have a Ph.D. and a strong interest in undergraduate and master's level teaching as well as a commitment to developing an independent research program.

Please send your curriculum vitae, a summary of teaching abilities and a description of your research interests and arrange to have three (3) letters of recommendation submitted by April 1, 1989 to: **Dr. Jonathan Green, Chair, Department of Biology, Roosevelt University, 430 South Michigan Avenue, Chicago, Illinois 60605.**

Affirmative Action/Equal Opportunity Employer

(NW3387)A

## UNIVERSITY OF BRISTOL DEPARTMENT OF PHARMACOLOGY Lectureship in Molecular Pharmacology

A Lectureship in Molecular Pharmacology is available under the NAAS Scheme. Applicants will be expected to assist in a broad range of teaching to science and medical undergraduates and in advanced teaching to final year Honours students. It is hoped that the person appointed will have research interests in an area of molecular pharmacology with experience in molecular graphic techniques being preferred but not essential.

Pursuit of the candidate's research interests will be strongly encouraged and it is hoped that he/she will work in association with the newly established Molecular Recognition Initiative in the Bristol Medical Sciences Building.

The NAAS Scheme is intended to create career opportunities for young academic staff at an early stage in their careers.

Starting salary in the range £9260 – £14500 per annum.

For further details telephone Bristol 303136 (ansaphone after 5pm) or write to the **Personnel Office, Senate House, Bristol BS8 1TH. Please quote reference TLJ3.**

Closing date 20 March 1989.

(8564)A

## **GS-13 Biochemist**

### **Biological Response Modifiers Program, DCT, NCI**

The Laboratory of Molecular Immunoregulation, Biological Response Modifiers Program, Division of Cancer Treatment, National Cancer Institute, National Institutes of Health, Public Health Service, is accepting applications for a biochemist position.

This position is available for an outstanding Ph.D., M.D. investigator with expertise in protein purification and analysis procedures as well as a strong background in biochemistry and molecular biology. Incumbent will serve as a Senior Investigator responsible for planning biological, immunological and biochemical approaches to the questions of lymphocyte regulation of normal and abnormal human leukocyte development and function. Incumbent will exercise a high degree of independent judgment as to formulating research approaches and supervising other members of his/her laboratory research staff in attaining these objectives. Responsibilities include developing and teaching other members of his laboratory research staff as well as outside collaborators the techniques necessary to study the role of lymphocytes in the growth and maturation of normal leukocytes and their possible therapeutic use in man. Research interests should focus on analysis of the role of several important regulatory molecules, such as interleukin 1, tumor necrosis factor and chemotactic factors in the activation and development of biologically mature, normal leukocytes; the purification, identification and molecular cloning of new factors which affect leukocyte development, maturation and function; the production, and mechanisms by which these proteins are processed into functional molecules; the interactions of these proteins with substrates in the target cells; and the development of monoclonal and polyclonal antibodies to these target proteins for use in more sensitive assays and as screening

reagents for human leukemias. The incumbent must possess extensive experience in and thorough knowledge of all aspects of lymphocyte biology (production, purification, assays, functions) and immunology and demonstrate research potential and accomplishment as evidenced by scientific publications. Experience with application of basic research findings to clinical situations, in order to pursue the work along clinically important lines, are critical for the success of the research.

The position will be a Civil Service position with an annual salary between \$41,121 and \$53,460 (based upon experience). Incumbent will be eligible for all benefits including health insurance, life insurance options, vacation and sick leave.

Applicants should submit CV and three letters of recommendation to:

**Dr. Joost J. Oppenheim**  
**Chief, Laboratory of Molecular**  
**Immunoregulation**  
**Biological Response Modifiers**  
**Program**  
**Division of Cancer Treatment**  
**National Cancer Institute**  
**Frederick Cancer Research Facility**  
**Building 560, Room 21-89A**  
**Frederick, MD 21701-1013**  
**Telephone: (301) 698-1551**

U.S. CITIZENSHIP IS REQUIRED  
NIH IS AN EQUAL OPPORTUNITY EMPLOYER

*Deadline for applications is April 30, 1989.*

## PROGRAM OF EXCELLENCE IN MOLECULAR BIOLOGY

### New Investigator Positions

The National Heart, Lung and Blood Institute of the NIH has awarded the University of Cincinnati Medical Centre a "Program of Excellence in Molecular Biology". The goals of the University of Cincinnati Program are to provide skills development and research opportunities in the molecular biology of heart and lung. Specifically, the Program will concentrate on gene regulation and structure-function analysis of proteins which play a central role in heart and lung. In addition, the role these genes play in human health will be investigated. The skills development program includes a 5 year program, initiating at the postdoctoral level and progressing to junior faculty status in the final years. New Investigators will initially work closely with the sponsor but in the final year will develop a research problem separate from that of the sponsor, and apply for independent funding to enable the Investigator to move to another institution if desired.

We are presently recruiting 12 such individuals with an additional twelve to be added in the second year. Ph.D.s or M.D.s with a strong background in molecular genetics who wish to apply their skills to significant problems of heart and lung or individuals with strong backgrounds in heart and lung who wish to develop molecular genetics tools for continued study of these problems are encouraged to apply. We are particularly interested in recruiting minorities to the Program. Stipends are competitive, beginning at £25,000 per year and moving to \$37,000 in final years. The core faculty are:

1. **Jerry Lingrel, Ph.D.** — Regulation of the Na,K-ATPase genes and RFLP analysis of diseases such as familial hypertension. Identification of the cardiac glycoside binding site using site specific mutagenesis.
2. **Jeffrey Whitsett, M.D.** — Characterization of lung surfactant proteins and genes.
3. **Winston Kao, Ph.D.** — Collagen gene expression in the lung.
4. **Gary Shull, Ph.D.** — Structure-function relationships and genetic regulation of Ca-transporting ATPases of intracellular and plasma membranes.
5. **Jeffrey Robbins, Ph.D.** — Study of cardiac contractile proteins and growth and developmental control of muscle and pulmonary proteins.
6. **Donal Luse, Ph.D.** — Transcriptional analysis of lung surfactant protein gene promoters.
7. **Steven Potter, Ph.D.** — Insertional mutagenesis for identifying critical genes in heart and lung development.
8. **Arnold Schwartz, Ph.D.** — Structure and function of Ca<sup>++</sup> channel proteins and gene regulation; isolation of receptors for calcium antagonists.
9. **Judith Harmony, Ph.D.** — Proteins and genes involved in neutral lipid transfer; the regulation of cell proliferation and differentiation by apolipoproteins.
10. **Thomas Doetschman, Ph.D.** — Gene targeting in ES cells using homologous recombinations. Focus will be on vasculogenesis, angiogenesis and cardiogenesis.

Applicants should submit a C.V. and the names of three references to **Jerry B Lingrel, Ph.D., Director, Program of Excellence in Molecular Biology, Department of Molecular Genetics, Biochemistry and Microbiology, University of Cincinnati College of Medicine, 231 Bethesda Avenue, Cincinnati, Ohio 45267-0524.**

*Affirmative Action/Equal Opportunity Employer*

(NW3379)A

## CALIFORNIA INSTITUTE OF TECHNOLOGY

### Junior Faculty Position in Geology

Applications are being accepted for a tenure-track Junior Faculty position in Geology in the Division of Geological and Planetary Sciences. The initial appointment is for four years. It is possible that a candidate with exceptional qualifications may be considered for a more senior position. Outstanding individuals with a strong commitment to original research and teaching in any areas of geology are encouraged to apply. We are particularly interested in scientists whose work relates to 1) tectonics/geophysics/structural geology, with special emphasis on the observational attack on current geologic processes as exemplified by those occurring over the past million years; and/or 2) the structure and origin of the deep continent crust. A bridging between geology and geophysics, to achieve the full advantages of applying geophysical understanding in field-oriented geological studies, is a highly desirable feature of the contemplated appointment. Individuals with potential for interactions with existing programs in geophysics and geochemistry are encouraged to apply.

A curriculum vitae including a list of publications and a brief description of proposed research activities should be sent to **Professor G. J. Wasserburg, Chairman, Division of Geological and Planetary Sciences, 170-25 (APA), California Institute of Technology, Pasadena, California 91125.**

*The California Institute of Technology is an Equal Opportunity/Affirmative Action Employer.* Applications are encouraged from qualified women and minority candidates. (NW3376)A

## UNIVERSITY OF EDINBURGH

### HIV RESEARCH

#### DEPARTMENTS OF CHEMISTRY AND GENETICS

### A Postdoctoral position

is available immediately for work on an investigation of the inhibition of HIV by phosphorothioate oligonucleotides, directed by Dr. Tom Brown (Chemistry) and Drs. A. J. Leigh Brown and J. O. Bishop (Genetics). Two main lines of research are planned: (1) An investigation of the mode of action of phosphorothioate and other oligonucleotides and (2) The identification of novel oligonucleotides with greater inhibitory effects in relation to cytotoxicity. Candidates should have a background in cell biology and preference will be given to those with experience of molecular biology and/or animal virology.

The appointment is available for three years, with salary in the range £9,865-£15,720 with maximum starting point of £13,870 for a suitably experienced candidate. Enquiries may be directed to 031-667-1081, Extension No. 3448 (T. Brown), 3551 (A. J. Leigh-Brown) or 3553 (J. O. Bishop), and applications, with full C.V. and names and addresses of two referees, should be sent to **Mr. A. Gillies, Department of Genetics, University of Edinburgh, West Mains Road, Edinburgh EH9 3JN, Scotland.** Please quote reference No. 5641. (8577)A

## UNIVERSITY OF BRISTOL

### Department of Biochemistry

### RESEARCH POSTS IN DNA-PROTEIN INTERACTIONS

Applications are invited for both a Post-Doctoral Research Fellowship and for a Graduate Studentship to work with Dr. S.E. Halford on the molecular mechanisms of DNA recognition by proteins. These include the *EcoRV* restriction enzyme, whose structure has recently been determined and is now available in this laboratory.

The fellowship is funded by the SERC for three years, starting from April 1st (though the start can be delayed for a suitable candidate), with an initial salary at the appropriate point on the RA1A scale (£9,865-£12,150). Prior experience in either molecular biology or protein chemistry/enzymology is desirable but not essential. The Studentship is also funded by the SERC and is available from October 1st. Please obtain further details on Bristol 303136 (answerphone after 5.00 p.m.) or write to Personnel Office, Senate House, Bristol BS8 1TH. Please quote reference A232.

Informal enquiries can be made to Dr. S.E. Halford on Bristol (0272) 303520.

*An Equal Opportunities Employer.*

# International Center for Agricultural Research in the Dry Areas (ICARDA)

## POSITION ANNOUNCEMENT HEAD, SCIENTIFIC INFORMATION SERVICE

ICARDA invites applications for this position at its main station in Aleppo, Syria.

ICARDA is one of the 13 international centers, supported by the Consultative Group on International Agricultural Research (CGIAR), a consortium of donor government's, international agencies and philanthropic foundations. It is concerned with agriculture in those regions that have a hot, dry summer and where cropping must begin in winter, the only season when rain falls. ICARDA has research programs dealing with cereals, food legumes, pasture, forage and livestock, as well as the management of farm resources. The Head Scientific Information Service is responsible for ensuring that the work and achievements of ICARDA are adequately reported to the scientific community and to the donors, and for providing an effective and up-to-date supply of scientific information to the researchers within ICARDA or collaborating with ICARDA.

### FUNCTIONS

The Head Scientific Information Service will report to the Deputy Director General (Research), and will be responsible for planning and supervising all operations of the program, which include public relations and the preparation of general-interest items, such as the Center's Annual Report. The sub-units involve editing and composition typing (English and Arabic), photography, graphic arts, printing, the Center's library, documentation, and specialized information services such as those on lentil, faba bean and cereals.

As the only international agricultural research center located in the region of West Asia and North Africa, ICARDA has special responsibilities to encourage networking and resource-sharing among the national agricultural information programs of the region, and to provide information from the region to meet the needs of CGIAR centers in other parts of the world.

### QUALIFICATIONS

Ideally, candidates will have had graduate training in agricultural science as well as in information science or journalism. All candidates must have held a position, for at least ten years, with management responsibility for the information function in a research environment. They must have extensive knowledge of the international mechanisms for sharing agricultural information and, preferably, will have had experience of working within an international organization and managing staff from a range of different cultures. The over-riding language qualification is for highly effective communication in English, both written and oral, but knowledge of Arabic or French would be an additional advantage.

### APPLICATIONS

Salary, other benefits, and general conditions of service are internationally competitive. Candidates with suitable qualifications are requested to send their applications and the names and addresses of two professional referees quoting Ref. No. STIP/2/88 to the **Deputy Director General (Research), ICARDA, P.O. Box 5466, Aleppo, Syria.**

Applications are accepted up to March 31st, 1989 or until a suitable candidate is selected.

(W5922)A

### UNIVERSITY OF LIVERPOOL Department of Earth Sciences

Applications are invited for two posts of postdoctoral Senior Research Assistant in the Department of Earth Sciences. The posts, tenable for three years from 1st April 1989, entail geological mapping and volcanological research in the Central Fells of the English Lake District. The work, with a team led by Dr. B.P. Kokelaar at Liverpool, and in collaboration with the B.G.S., will be in fulfilment of a NERC/BGS Mapping Contract. Informal enquiries may be made to Dr. Kokelaar. Tel. 051-794 5188.

Initial salary £9,865 per annum.

Applications, together with the names of three referees, should be received not later than 17 March 1989, by **The Director of Staffing Services (AS), The University, P.O. Box 147, Liverpool, L69 3BX**, from whom further particulars may be obtained.

Quote ref. RV/278/N

(8538)A

### UNIVERSITY OF DURHAM DEPARTMENT OF GEOLOGICAL SCIENCES LECTURER IN BASIN DYNAMICS (NAAS)

Applications are invited for a lectureship in Basin Dynamics, which is expected to be available under the UGC NASS Scheme in the expanding Department of Geological Sciences. Candidates should have proven research experience with a background in sedimentology/stratigraphy/structural geology. Preference will be given to persons with experience of working with or in the oil industry. Excellent opportunities exist for co-operative research in the fields of: palaeo- and neo-tectonics, the geophysics of lithospheric deformation and clastic and carbonate sedimentology.

The appointment may be made initially on either the Lecturer Grade A Scale (£9,260 – £14,500) or on the Grade B Scale (£15,105 – £19,310).

Further particulars may be obtained from the **Registrar, Science Laboratories, South Road, Durham, DH1 3LE (Tel. No. (091) 374 2263)** to whom applications (three copies), including the names of three referees, should be sent not later than **Monday, 3rd April, 1989** (quoting ref. GL1).

(8599)A

## Cruachem

### POSTDOCTORAL CHEMIST Nucleoside/Oligonucleotide Synthesis

Cruachem Ltd is a small but growing company which has built a world-wide reputation in the field of DNA synthesis.

Following our move to purpose-built laboratories at the West of Scotland Science Park on the outskirts of Glasgow, we now require a Postdoctoral Chemist to participate in our active Research and Development effort.

The successful applicant will be involved in a variety of projects, including evaluation and optimisation of the performance of DNA synthesizers and of the methodology of DNA synthesis, laboratory-scale synthesis of nucleoside derivatives and testing of computer software for the control of laboratory instruments.

Ideally, candidates should have some experience of the use of automated DNA synthesizers as well as hands-on experience of the synthesis of nucleoside analogues and derivatives, although candidates with experience in only one of these fields will be considered. Familiarity with the operation of IBM-compatible personal computers would be an advantage, as would a broad understanding of the applications and uses of synthetic oligonucleotides in Molecular Biology and Biochemistry.

In addition to a competitive starting salary, there is a good benefits package, including reimbursement of relocation expenses if necessary.

Please apply in writing, enclosing a comprehensive Curriculum Vitae to:

**Ian Wilkie,  
Chief Executive,  
Cruachem Ltd,  
Todd Campus,  
West of Scotland Science Park,  
Acre Road,  
GLASGOW G20 0UA.**

(8507)A

# THE UNIVERSITY OF BIRMINGHAM

## NEW ACADEMIC APPOINTMENTS SCHEME

Following the initiative by the UGC to create opportunities for young new academic staff, the University expects to be able to offer lectureships in the following subjects for October 1989:

### School of Biochemistry

#### Lecturer in Protein Biophysics (Reference BC 4310)

The appointee will have established expertise in one or more approaches to the study of protein-protein, protein-DNA or protein-ligand interaction. Research interests related or complementary to those already in the School of Biochemistry and/or experience in protein engineering would be an advantage.

### School of Computing and Computer Science

#### Lecturer in Systems Analysis and Design (Reference CS 4311)

Lecturer required to specialise in research, teaching and project supervision primarily in the area of systems analysis and design.

### School of Physics and Space Research

#### Lecturer in Solar and Stellar Physics (Reference PH 4312)

To study the seismology of the Sun and Stars using Doppler spectroscopy and photometric techniques at various observational sites around the world.

#### Lecturer in Environmental and Biomedical Physics (Reference PH 4313)

To study low level dosimetry and to develop biomedical applications of imaging.

#### Lecturer in Chemical Physics (Reference PH 4314)

To investigate reaction rates of ionic atoms and molecules present in upper atmosphere and interstellar plasmas.

Although there is no upper age limit for candidates, it is the intention of the Scheme to enable Universities to recruit younger academic staff. Salary will be within Lecturer A Scale £9,260 – £14,500.

Application forms and further particulars are available from: **The Senior Assistant Registrar (Science), The University of Birmingham, P.O. Box 363, Birmingham, B15 2TT. Applications (three copies) should be returned by 31st March.**

**AN EQUAL OPPORTUNITIES EMPLOYER**

(8582)A

## ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND

### Anatomical Society Research Studentships

Applications are invited from Departments of Anatomical Sciences in the UK and Ireland for Research Studentships tenable in the Anatomical Sciences for a period up to three years. Students nominated by Departments must be graduates of British or Irish Universities and will be expected to register for a higher degree. The stipend will be commensurate with basic Research Council rates.

### Anatomical Society Senior Visiting Fellowship

Applications are invited from Overseas Scientists for one Fellowship tenable for a period of less than a year in a Department of Anatomical Sciences in the UK or Ireland. Applicants should be of post-doctoral or comparable status and must have arranged sponsorship in the Department in which they intend to work. Some assistance towards travel and subsistence will be provided.

Further particulars should be obtained from the Acting Secretary, Dr Ian Whitmore, Department of Cell and Structural Biology, Stopford Building, University of Manchester, Oxford Road, Manchester M13 9PT, to whom applications should be sent by 28 April 1989.

(8606)A

## NMR Spectroscopist

### Center for Advanced Research in Biotechnology

The Center for Advanced Research in Biotechnology (CARB) is seeking an NMR spectroscopist to fill a faculty level, tenure track position of the University of Maryland. The successful candidate will be especially interested in using NMR methods to study macromolecular structure and function, and will be expected to build a vigorous research program. The level of the appointment is open, depending on background and experience.

**CARB's Mission:** CARB is joint basic research venture between the University of Maryland and the National Institute of Standards and Technology. (NIST, formerly the National Bureau of Standards). Our goal is to build a center of 27 research excellence in the area of protein structure, function, engineering and design. CARB's new 40,000 Sq. ft. research facility is situated just outside Washington DC, on the newly established Shady Grove Campus of the University of Maryland, and in the heart of Maryland's rapidly growing biotechnology community.

**State-of-the art Labs:** CARB has developed groups in protein crystallography, macromolecular theory and modeling, molecular biology and physical biochemistry, and is now focusing on developing a strong research program in the use of NMR techniques to study protein structure and function. Our labs are equipped with state-of-the art instrumentation, including a minisupercomputer, microvaxs, and several graphics workstations. The University has committed to the purchase of a 500MHz instrument in FY 1989 to enhance the development of CARB's NMR group.

Please send a current CV, an outline of future research interests and goals, a list of individuals who will serve as references, and request that at least three letters of reference be sent to **The CARB NMR Search Committee, CARB, 9600 Gudelsky Drive, Rockville, MD 20850.**

*The University of Maryland is an equal opportunity employer.* (NW3375)A

## THE SCHOOL OF PHARMACY UNIVERSITY OF LONDON

### Fixed-term Lectureship in Pharmaceutical Chemistry

Applications are invited for a fixed-term Lectureship in the Department of Pharmaceutical Chemistry. The appointment is available immediately and is for a period up to and including September 1991. The successful candidate will be required: (i) to teach biochemistry to undergraduate students (ii) to participate in biochemistry practical classes and (iii) to pursue research in the field of receptor biochemistry. Experience in protein chemical methods/antibody production would be an advantage but is not essential.

The salary will be according to the scale for University Lecturers (Grade A £9,260 – £14,500; Grade B £15,105 – £19,130 plus £1,650 London Allowance). Applications in the form of a curriculum vitae and the names of at least two referees should be sent as soon as possible, and by no later than the end of March to **Mr N J Rampley, Assistant Secretary, The School of Pharmacy, University of London, 29-39 Brunswick Square, London WC1N 1AX.** (8561)A

## CELL BIOLOGIST/BIOCHEMIST

with a strong interest in breast cancer, to establish a program in growth factor/oncogene research. Selection will be based upon experience, proven ability to develop an independent program as evidenced by current grant support and willingness to interact with established programs in a multidisciplinary approach. Expertise in primary culture of human and rodent cells desirable. Core support for the program will be provided by the Michigan Cancer Foundation (rank commensurate with experience).

Submit curriculum vitae, three references, and summaries of current and future research plans by 1 June 1989 to: **Dr. Gloria Heppner, Michigan Cancer Foundation, 110 East Warren, Detroit, MI 48201.**

# Public Perception for Biotechnology and Seeds

For our Agricultural Division we seek a recently qualified Ph.D. scientist who has the expertise to contribute to the Seeds Subdivision efforts in public perception and external relations regarding the areas of agricultural biotechnology and seed-related issues.

Candidates are expected to have a sound knowledge of molecular biology, plant biology and genetics, as well as the ability to defend viewpoints and debate issues in national and international organisations. Proficiency in written and spoken English and German is a necessity; a knowledge of French would be useful.

Please send your application quoting ref. "Nature 223" to M.A. Vogel, Personnel Department, CIBA-GEIGY Ltd., P.O. Box, CH-4002 Basle.

## CIBA-GEIGY

### BAKER MEDICAL RESEARCH INSTITUTE POST DOCTORAL FELLOW

Applications are invited for the above mentioned position in the Biochemical Pharmacology Laboratory. The successful applicant will join an active group studying the regulation of membrane ion transport processes blood vessels and the causes of cardiovascular hypertrophy in hypertension, using a variety of techniques which include cell culture, intracellular fluorescence spectroscopy and M-RNA analyses.

Applicants should have recently obtained or about to complete a PhD degree in biochemistry, physiology, pharmacology or closely related discipline. Current salary A\$28,000 pa. Applications (including C.V. and two letters of reference) or enquiries, should be addressed to

**Dr. A. Bobik,**  
**Baker Medical Research Institute,**  
**P.O. Box 348,**  
**Prahran, Victoria**  
**3181, Australia.** (W5923)A

### WASHINGTON UNIVERSITY SCHOOL OF MEDICINE ST. LOUIS, MISSOURI DEPARTMENT OF PHARMACOLOGY CHAIRPERSON

Applications and nominations are invited for the position of Chairperson of the Department of Pharmacology. Candidates should be distinguished as scholars and scientists with demonstrated commitment to medical and graduate education.

Curriculum vitae and bibliography may be submitted to:

**M.K. King, M.D.**  
**Dean**  
**Washington University School of Medicine**  
**660 South Euclid — Box 8106**  
**St. Louis, Missouri 63110**

### UNIVERSITY OF EDINBURGH

#### Department of Chemistry Lectureship in Organic Chemistry

Applications are invited for the above Lectureship for which the University has sought funding under the UGC's New Academic Appointments Scheme, with effect from 1st October 1989. Under the terms of the scheme, which is intended to provide permanent appointments for young staff, preference will be given to candidates at an early stage in their careers.

Candidates should have achievement and continuing interest in biological aspects of organic chemistry, and should be prepared to outline their short and medium term research objectives. The person appointed will be expected to undertake a normal level of undergraduate teaching of general organic chemistry.

The initial salary will be on Lecturer A scale (£9,260-£14,500) or, exceptionally on Lecturer B scale (£15,105-£19,310).

Applications, giving full details of career, a list of publications and the names of two academic referees should be submitted to the **Personnel Office, University of Edinburgh, 63 South Bridge, Edinburgh EH1 1LS** by 28th April 1989. Please quote reference No. **NAAS 2010.** (8551)A

### THE UNIVERSITY OF THE WEST INDIES

Cave Hill Campus, Barbados

### CENTRE FOR RESOURCE MANAGEMENT AND ENVIRONMENTAL STUDIES

Applications are invited for the following new posts in the Centre for Resource Management and Environmental Studies at the Cave Hill Campus of the University of the West Indies, Barbados, to teach at the postgraduate level in a multi-disciplinary programme leading to Diploma and Masters level certification.

(1) FISHERIES AND RESOURCE MANAGEMENT; (2) COASTAL ZONE MANAGEMENT; (3) RESOURCE ECONOMIST; (4) BIOGEOGRAPHER/PLANNER. The posts at (1), (2) and (3) are at the level of Senior Lecturer/Lecturer. Depending on the qualifications and experience of the applicants two appointments may be made at the level of Senior Lecturer. Appointment to the post at (4) will be at the level of Lecturer. For all four posts proven research ability and capacity to attain grant funding are essential and the ability to teach data management, a knowledge of microcomputer systems and Caribbean or other tropical experience are highly desirable. The successful applicant will be expected to assume duties as soon as possible.

**SALARY SCALES:** SENIOR LECTURER BD\$50,712 × 1644-60,576 × 1776-65,904 (B) × 1776-69,456 p.a. LECTURER: BD\$38,208 × 1644-48,072 (B) × 1644-57,936 p.a. Up to five full economy class passages plus baggage allowance of US\$1200 on appointment and normal termination. Special allowance up to US\$400 for shipment of academic books and teaching/research equipment on appointment. Unfurnished accommodation of 10% of basic salary, or optional housing allowance of 20% of basic salary to staff making own housing arrangements. UWI contribution of equivalent of 10% of basic salary to Superannuation Scheme. Annual Study and Travel Grant for self, spouse and up to three children. Book Grant up to BD\$720 per annum. Detailed applications (three copies) giving full particulars of qualifications and experience, date of birth, marital status and the names and addresses of three referees should be sent as soon as possible to the Campus Registrar, University of the West Indies, PO Box 64, Bridgetown, Barbados. The University will send further particulars for these posts to all applicants. These particulars may also be obtained from Appointments (36070), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF. (W5921)

# Senior Research Biologist

## Department of Cellular Science

**From £15k inclusive**

**Greenford, Middlesex**

Glaxo Group Research is an expanding Company dedicated to the research and development of medicines to treat human diseases. As part of our continued expansion, a new vacancy has been created within a section of the Department of Cellular Science, who are working on the pathophysiology of various conditions including cancer, skin diseases, connective tissues and diabetes.

We are looking for a Senior Research Biologist to lead a small team, and provide initiative and innovation in developing models of disease states, as well as maintaining established screening programmes.

Ideally you will have several years' experience, working with *in vivo* models of disease states.

In return you can expect to receive a highly competitive salary (depending on your experience) along with all the benefits you would associate with a major organisation, such as guaranteed bonuses, flexible working hours, and relocation assistance where appropriate.

**Please send a full c.v. or telephone for an application form to: Personnel Officer, Glaxo Group Research, Greenford Road, Greenford, Middx UB6 0HE. Telephone 01-422 3434, ext. 2934, quoting reference no. G89043.**

(8612)A

# Glaxo Group Research

## PLANT-MICROBE MOLECULAR BIOLOGISTS

The Department of Microbiology at the University of Vermont is continuing to expand its research base in molecular biology. Tenure track positions at the assistant and/or associate professor level are available in areas of molecular microbiology relevant to the agricultural sciences. Areas of interest include, but are not limited to, 1) molecular aspects of microbe-plant interactions (including viral, bacterial and fungal pathogens and symbionts) and 2) molecular biology of photosynthetic microorganisms. Applicants' research programs are expected to address questions that relate to gene structure, expression or function. A Ph.D. and postdoctoral experience are required. The Department will be housed in a new Microbiology Center currently under construction. Startup funds and interim renovated space are available. Faculty members hold appointments in both the College of Agriculture and Life Sciences and the College of Medicine. The Department's primary emphasis is on research; teaching responsibilities are to undergraduate, graduate and medical students.

The University of Vermont enrolls approximately 10,000 students and is ranked among the top 'Public Ivies' for its academic excellence and agreeable atmosphere. Scenically located near the Green Mountains and on the shores of Lake Champlain, Burlington offers excellent cultural and recreational opportunities as well as proximity to Montreal and Boston.

Send nominations and applications with curriculum vitae, present and future research plans and at least three letters of reference to:

**Search Committee  
Department of Microbiology, Given Building  
University of Vermont, Burlington, Vt. 05405**

Review of applications will begin immediately and continue until the positions are filled. *An Equal Opportunity/Affirmative Action Employer.* Women and minorities are especially encouraged to apply. (NW3364)A

**Board of the Swiss Federal Institutes of Technology**

**Paul-Scherrer-Institute, Villigen/Würenlingen,  
Switzerland**

## DIRECTOR

Applications are invited for the position of Director of the Paul-Scherrer-Institute (PSI) in Würenlingen/Villigen, Switzerland.

The PSI is a federal multidisciplinary research organization (1000 employees) that conducts research in elementary-particle and nuclear physics, solid-state physics, life science, and energy engineering, both nuclear and non-nuclear. It develops and operates advanced research facilities in support of Swiss universities and international research organizations.

The Director is responsible for the scientific, technical and administrative management of the PSI, and normally assumes auxiliary duties on the faculty of the Swiss Federal Institute of Technology in Zürich or the Swiss Federal Institute of Technology in Lausanne.

Candidates for the position of Director should have a strong record of leadership in either a university or an industrial environment. They should also hold an advanced degree, have demonstrated competence in physical, chemical, biological or engineering research, and be reasonably fluent in German, French and English.

The new Director is expected to assume his or her duties in spring 1990. Applications should be submitted by May 31, 1989, to the **President of the Board of the Swiss Federal Institutes of Technology, ETH-Zentrum, CH-8092 Zürich, Switzerland.** (W5915)A

## University College London

### NEW ACADEMIC APPOINTMENTS SCHEME

University College London is seeking 18 young, gifted people to fill lectureships from 1 October 1989 for which funds have been sought from the UGC under the NAAS. Applications are invited in the following areas each of which has a record of eminent achievement in teaching and research:

#### **Earth Remote Sensing**

**Department of Physics & Astronomy**

Global observations of the Earth from satellites represents the biggest growth area in modern space science and is important for environmental as well as research and teaching purposes.

#### **Inorganic Chemistry**

**Department of Chemistry**

For this Lectureship in Chemistry candidates should have special interests in the teaching of inorganic chemistry and in research in any area of inorganic chemistry.

#### **Engineering Sedimentology**

**Department of Geological Sciences**

Applicants should have an interest in the influence of diagenesis on engineering and reservoir characteristics of sedimentary rocks.

#### **Computer Modelling of Cognition**

**Department of Psychology**

Candidates should have an interest in the computational modelling of cognitive processes and will be expected to possess or develop skills in connectionist modelling.

#### **Human Genetics**

**Galton Laboratory, Department of Genetics & Biometry**

Applicants should have a broad training in human genetics, be involved in some aspect of the Human Genome Project and be able to share in both elementary and specialist teaching.

#### **Environmental Design and Engineering**

**Bartlett School of Architecture & Planning**

A Lecturer is required to maintain the strength of this central area of the School.

#### **System Design and Development**

**Centre for Information Technology**

To contribute to teaching and research on the definition, design, development, use and evolution of complex computer based systems in a new Centre formed jointly by the Department of Electrical and Electronic Engineering and the Department of Computer Science.

#### **Chemical Engineering Design**

**Department of Chemical & Biochemical Engineering**

Mainstream chemical engineer with design and/or research experience and interest in C.A.D.

#### **Developmental Neuroscience**

**Department of Anatomy & Developmental Biology**

This appointment is needed to maintain the Department's exceptional strength in this growth area.

#### **Protein Chemistry**

**Department of Biochemistry**

Physical biochemist interested in the relation between sequence and the three-dimensional structure and the function of proteins, including those in membranes.

#### **Non-Clinical Chemical Pathology**

**Department of Chemical Pathology**

Non-clinical Lecturer required with a higher qualification and experience in the discipline to conduct research relevant to existing interests in the department and to share in undergraduate and postgraduate teaching.

The salaries will be within Lecturer A, £10,910 - £16,150 inclusive. Further particulars for each appointment from Jacquie Worrall, Telephone: 01-380 7102. Applications, including C.V. and the names and addresses of three referees by **20 March 1989** to the Assistant Secretary (Personnel), UCL, Gower Street, London WC1E 6BT. UCL is an Equal Opportunities Employer.

(8607)A

### **MOLECULAR TUMOR BIOLOGY**

#### **A POSTDOCTORAL/RESEARCH ASSOCIATE POSITION**

is available immediately for candidate with background in one or more of the following areas: Molecular biology, Genetic engineering, Radiation biology, Biochemistry, Virology or Immunology. Candidate will participate in research on the molecular basis of radiation-resistant human cancers with special focus on PCR-based evaluation and comparison of the oncogene sequence(s) in normal vs. tumor cells.

Please send curriculum vitae to: **Dr Anatoly Dritschilo, Professor and Chairman, Department of Radiation Medicine, The Vincent T. Lombardi Cancer Research Center, Georgetown University Medical Center, 3800 Reservoir Road, N.W., Washington, D.C. 20007.**

Equal Opportunity/Affirmative Action Employer.

(NW3358)A

### **ASSISTANT PROFESSOR**

#### **Haverford College**

Haverford College, 2-year position as Assistant Professor to teach molecular and biochemical biology, immunofluorescence or electron microscopy, and direct student research.

Contact: A. G. Loewy, Haverford College, Haverford, PA 19041. Deadline for applications March 23.

Equal Opportunity Employer/Affirmative Action. (NW3403)A

### **THE UNIVERSITY OF TASMANIA**

#### **INSTITUTE OF ANTARCTIC AND SOUTHERN OCEAN STUDIES (IASOS)**

Applications are invited from suitably qualified men and women for the following position.

#### **ODP SUPERVISING SCIENTIST** (Ref. 41/89)

Australia has become a joint member with Canada of the Ocean Drilling Program, and the Australian ODP Council has nominated the University of Tasmania as the site for the Australian ODP Secretariat for the next three years. The ODP Secretariat will be attached to the University's Institute of Antarctic and Southern Ocean Studies.

The ODP Council seeks a geoscientist, to be appointed at a senior level, as ODP Supervising Scientist. The successful applicant will be primarily responsible for the day-to-day management of Australia's involvement in ODP, will participate in the planning of its scientific program, and will also have research and some teaching responsibilities in the University's Department of Geology, which has vigorous research groups concerned with ocean floor magmatism and geochemistry, and with marine geological studies of the SW Pacific and NE Indian Oceans. Applicants in the field of marine geophysics will be particularly welcome.

The position will be funded for three years at the first instance, at the Reader level, currently \$53,670 per year. Applications should include a complete resume with the names of three referees, and a statement of current research interests.

Further information may be obtained from Professor D.H. Green (tel. 61.02.202477), Dr. R. Varne (tel. 61.02.202468) and by writing (Fax 61.02.202186) to The Director, Institute of Antarctic and Southern Ocean Studies, the University of Tasmania, G.P.O. Box 252C, Hobart, Tasmania 7001, Australia.

Position information and application forms available from the Staff Office Secretary, tel. (61.02) 202013. Applications quoting ref. should be sent to the Staff Officer, University of Tasmania, G.P.O. Box 252C, Hobart, Tasmania 7001, Australia, by 31 March 1989.

The University is an Equal Opportunity Employer (W5918)A

**nature**  
— the professionals' choice

**At the Swiss Federal Institute of  
Technology in Zurich the chair of  
FOOD MICROBIOLOGY  
is to be filled.**

Duties of the new professor include teaching and research in the general field of food microbiology. Applicants will have a university degree in food science, food microbiology or microbiology and several years of successful independent research and development work in food microbiology.

Enthusiasm to teach at all university levels and willingness to interact with colleagues within and outside the university are indispensable.

Candidates should address their application with curriculum vitae and list of publications no later than **April 30, 1989**, to the **President of ETH Zurich, Prof. Dr. Hans Bühlmann, ETH-Zentrum, CH-8092 Zurich. (W5917)A**

SYNTHELABO RECHERCHE (L.E.R.S.)

**Head of the Cerebral Circulation  
& Metabolism Group**  
**Biology Department**

SYNTHELABO RECHERCHE (L.E.R.S.) is the Division responsible for research and development in this leading French pharmaceutical company with rapidly expanding international interests.

The position involves the scientific direction of a group of about 15 scientific staff with opportunities for undertaking original research within a scientifically stimulating environment in well-equipped and newly built laboratories situated 5 km from the centre of Paris.

The successful candidate should have several years post-doctoral experience and have made a substantial contribution in the fields of cerebrovascular and neuroprotective research.

Experience in the pharmaceutical industry and a basic knowledge of French would be useful but not essential.

Please write, in confidence, with a detailed curriculum vitae to:  
M. Campionnet, Human Resources Department  
SYNTHELABO RECHERCHE (L.E.R.S.)  
58 rue de la Glacière 75013 Paris, France.

(L.E.R.S.)

(W5934)A

L.R.W.

**Senior Appointment in  
Research Management**

The Medical Research Council wishes to appoint an experienced scientist or medical practitioner to the staff of its headquarters office in Central London, to play a major part in new arrangements for the central management of research funding. Reporting to the Head of Medical Division, and through him to the Secretary and Second Secretary of the Council, the new appointment would have two main areas of responsibility:

■ the development and implementation of policy on a wide range of research topics which cross the boundaries of the MRC's individual research boards. Initially, this will include substantial involvement with the scientific planning of the New National Centre for Multispeciality Postgraduate Medical Education and Research which the Council is proposing to set up at Hammersmith in partnership with the Royal Postgraduate Medical School.

■ management of the headquarters office Grants and Training Awards Group, which administers the Council's grants and training awards schemes for the support of research and research workers in universities, polytechnics, hospitals and independent research institutes. The person appointed will be expected to play a major role in reviewing and developing these scheme and in liaising with higher education and research institutions.

The post is likely to be of interest to scientists with a substantial track record in biomedical research together with significant managerial experience. The Council would be particularly interested to hear from clinically-qualified candidates but non-clinical scientists are equally encouraged to apply.

Appointments to the Council's headquarters staff are usually for a probationary period at the end of which they may be made permanent. In this case, the Council would also be prepared to consider a fixed term contract for someone interested in secondment from their present employer. The salary payable to non-clinical staff is on Civil Service Grade 6, £21,633-£32,826 (plus London Weighting £1,750 p.a.) There is a separate salary scale for clinically-qualified candidates rising to £36,786 (plus London Weighting £1,750). In addition, a 4½% supplement is payable to members of the MRC Pension Scheme.

**Application forms and further information about the post are available by telephoning or by writing to Miss Kathryn Fenn in the Headquarters Office Staffing Group, Medical Research Council, 20 Park Crescent, London W1N 4AL (01-636 5422 x 404).**

**the closing date for applications is 10 April 1989. Reg. No. 185725 VAT No. 238 6105 65**

**MRC**

Medical Research Council

(8583)A

**UNIVERSITY OF CAMBRIDGE  
DEPARTMENT OF EARTH SCIENCES  
ASSISTANT DIRECTORSHIP OF RESEARCH  
IN MARINE GEOPHYSICS**

Applications invited for Assistant Directorship of Research from workers with experience of proposing, organising and running research cruises, and some involvement in instrument development in any area of marine geophysics.

Salary scale £12,760-£19,310.

Further particulars from the **Administrator, Department of Earth Sciences, Downing Street, Cambridge CB2 3EQ**, to whom applications, with a c.v. (10 copies), and names of three referees, should be sent by **2 May, 1989.**

## MINISTRY OF AGRICULTURE, FISHERIES AND FOOD

Food Science Division  
London

### Head of Food Microbiology Branch

You will be responsible for the day-to-day and long-term administration of the Branch. You will generate and present scientific and technical advice on food microbiology and represent the Ministry at both national and international meetings.

You should have a good degree in microbiology with extensive post-graduate experience in food microbiology, preferably with experience of research and the food industry.

Starting salary will be in the range £18,440-£23,485 (including £1750 Inner London Weighting) with further increments, depending on performance, up to £27,670. Ref: S(E)677

### Food Microbiologist

You will deputise for the Head of the Food Microbiology Branch and assist him in the generation and presentation of scientific and technical advice on food microbiology. You will provide briefing to senior members of staff who attend national and international meetings and you may stand in for the Head of Branch at these meetings. You will also be involved in the co-ordination of the scientific aspects of MAFF's activities in relation to food poisoning incidents.

You should have a good degree in microbiology with at least 4 years' relevant post-graduate experience, preferably with experience of research and the food industry.

Starting salary will be in the range £14,690-£18,780 (including £1750 Inner London Weighting) with further increments, depending on performance, up to £21,675. Ref: SB/12/AE

RELOCATION EXPENSES UP TO £5000 MAY BE AVAILABLE FOR BOTH POSTS.

For further details and an application form (to be returned by 17 March 1989) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 468551 (answering service operates outside office hours). Please quote appropriate reference.

### A F B – Arzneimittelforschung GmbH in Berlin

AFB – Arzneimittelforschung Berlin GmbH in Berlin is a drug research company rapidly growing both nationally and internationally.

In the Department of Biometry and Statistics we are looking for a

### Senior Biostatistician

to work in our Head Office in Berlin (West).

The ideal candidate has a degree in Mathematics or Statistics from a recognized University and at least five years working experience in the pharmaceutical industry or in a medical research or health institution. Apart from a thorough knowledge of statistical methodology, he or she should be familiar with statistical software packages such as SAS and SPSS and their application on main frames and PC networks. Experience is also required in the preparation of technical reports (in English). A working knowledge of German is desirable or at least the willingness to learn German quickly. We offer a competitive salary commensurate to experience, and excellent opportunities for career development.

Please send your application to the **personnel manager**.

### UNIVERSITY OF BIRMINGHAM SCHOOL OF BIOLOGICAL SCIENCES

#### Temporary Lectureship (Ref: BS2005)

A position is available for three years for a Temporary Lecturer to work in collaboration with the group of Professor Nigel Brown in the new School of Biological Sciences (the former Departments of Genetics, Microbiology, Plant Biology and Zoology). Preference will be given to applicants wishing to work on the mechanisms of heavy metal metabolism and resistance in microorganisms, but the overriding criterion will be academic excellence. The successful applicant will have opportunity to develop independent research programmes. The appointment will be on the Lecturer 'A/B' scale, £9,260-£19,310, plus super-annuation.

For an informal discussion on the position, please contact Professor N L Brown, (telephone 021-414 6556, Fax 021-414 5925).

For further particulars of the above post and an application form, telephone 021-414 6383 quoting reference number BS2005. Applications (3 copies) should be sent to the **Senior Assistant Registrar, Faculty of Science, PO Box 363, Birmingham B15 2TT** by 21st April 1989.

### UNIVERSITY OF CAMBRIDGE DEPARTMENT OF EARTH SCIENCES UNIVERSITY LECTURERS OR ASSISTANT LECTURERS IN ENVIRONMENTAL CHANGE

These will be joint appointments with the Sub-Department of Quaternary Research.

For one of the posts, preference will be given to applicants working on problems of Recent Earth (including ocean) history or behavior, using or developing physical, chemical, isotopic or geochronological methods.

For the other, preference will be given to applicants working on microfossils in palaeoenvironmental, evolutionary or bio-chronological studies.

Appointment at Lecturer or Assistant Lecturer level, according to age. Lecturer salary scale £13,365 – £20,626. Assistant Lecturer salary scale £10,460 – £14,500.

Further particulars from the **Administrator, Department of Earth Sciences, Downing Street, Cambridge CB2 3EQ**, to whom applications, with a c.v. (10 copies), and names of three referees, should be sent by **2nd May, 1989**. (8554)A

# Protein Crystallographer

There is a vacancy for a protein crystallographer in a newly formed Drug Design Group in the Pharmaceutical Division at Sandoz.

We are committed to an extensive basic research program involving X-ray structure analyses of medicinally/pharmacologically important proteins and protein drug complexes. X-ray equipment will include an area detector, rotating anode generator and computer graphics. There is also close collaboration with NMR and molecular modelling groups, providing an ideal environment for joint drug design projects.

Applicants should have a PhD and experience in most aspects of protein crystallography.

*If you are interested please send your application with a detailed C.V. to:*

UNIVERSITY OF EXETER (U.K.)  
UNIVERSITAET MARBURG (F.R.G.)  
INSTITUT JACQUES MONOD (PARIS)  
**POST-DOCTORAL CHEMISTS/  
BIOCHEMISTS/MOLECULAR  
BIOLOGISTS**

Applications are sought from chemists, biochemists and molecular biologists for 3 post-doctoral vacancies funded by a major collaborative grant under the European Community's SCIENCE Programme for 3 years from 1 April 1989, or as soon as possible thereafter. The project concerns biochemical characterization of insect steroid (ecdysteroid) hormone receptors and the receptor gene. The collaborating groups are those of Professor J. Koolman (Marburg), Dr. J.-A. Lepesant (Paris) and Dr. L. Dinan (Exeter). One vacancy exists at each centre, with the vacancies in Exeter and Marburg being suitable for applicants with a background in chemistry and/or biochemistry and the Paris vacancy appropriate for a molecular biologist. Previous research experience of steroid hormones, receptors, monoclonal antibody production, modern protein purification methods or molecular biological techniques advantageous. Applicants for each post must be nationals of another European Community country other than the one in which the research centre is located. Salaries will be on the national scale appropriate for the country involved. Travel funds are available for research visits and discussion meetings between the collaborating laboratories.

Applications (3 copies), including details of previous experience, a list of publications, the names of 3 referees and stating which post(s) you wish to be considered for, should be sent to **Dr. L. Dinan, Department of Biological Sciences, University of Exeter, Perry Road, Exeter, Devon EX4 4QG, U.K.**, within four weeks of the appearance of this advertisement. It would be helpful if applicants could also send copies of the publications which they regard as most representative of their research to date. Further particulars obtainable from Dr. Dinan (Tel: (0392) 264605/264603, Fax: (0392) 263108, Telex: 42894 EXUNIV G). (8493)A

## Faculty Positions in X-ray Crystallography

The Department of Biological Chemistry and Molecular Pharmacology at Harvard Medical School and the Dana-Farber Cancer Institute are seeking applications to fill two positions at the **Assistant Professor** level to be located at the Dana-Farber Cancer Institute. Applicants should be interested in using crystallographic methods to solve problems in Structural Biology and Biochemistry and should have an appropriate combination of related graduate and postdoctoral level research experience. Interested applicants should send an outline of future research plans, a curriculum vitae, bibliography and the names of three to four references to: **Professor Christopher Walsh, Chairman, Biological Chemistry and Molecular Pharmacology, Search Committee, Harvard Medical School, 240 Longwood Avenue, Room C1-213, Boston, MA 02115. Women and minorities are encouraged to apply. Harvard University and Dana-Farber Cancer Institute are Equal Opportunity Employers.** (NW3386)A

## POSTDOCTORAL POSITION IN MOLECULAR BIOLOGY UNIVERSITY OF CALIFORNIA, SAN DIEGO

available to study a novel system of regulation of gene expression and DNA replication by silicon in a lower eukaryote, by analysis of gene banks. Cloned yeast genes have been used successfully to identify diatom genes of similar function and at least one yeast mutation *leu 2<sup>-</sup>* has been complemented using cloned diatom DNA sequences. Background in molecular biology. Proficiency in recombinant DNA techniques: cDNA cloning, analysis of gene banks, vector construction, Southern and Northern hybridization, transformation, analysis of regulatory sequences, DNA sequencing. Salary starting at \$25,332 to \$27,624, depending on qualification. Send detailed CV and three names for reference to: **Dr. B. E. Volcani, Scripps Institution of Oceanography, University of California, La Jolla, CA 92093, tel (619) 534-2194.** Applications will be accepted until positions are filled. *An Equal Opportunity/Affirmative Action Employer.* (NW3396)A

# ENTOMOLOGIST BIOLOGICAL PEST CONTROL

Chr. Hansen's Bio Systems A/S urgently seek an entomologist for our Biological Pest Control Section, Biopax. The position involves support for technical/sales functions in dealing with the production and practical application of beneficial insects and micro-biological control products.

**We are involved** in the development, propagation and marketing of biological products, the bulk of which are sold in Scandinavia.

Applicants should have a degree in entomology or ecology, preferably with experience of research in the use of beneficial insects and population biology, combined with either practical experience of horticulture or a good understanding of horticulture practice. In selecting suitable candidates we shall place emphasis on analytical skills and project management experience.

The position involves close cooperation with technical services/sales, marketing, product development and production. The ability to form good working relationships with colleagues is essential.

**We are seeking** a dynamic person who can deal with production and with further development of existing products, and who can initiate research into new products.

If, and when, time permits, additional short or long term projects will be added to the job function. In the longer term it is expected that the job function will change in a more development oriented direction.

The successful applicant will be based at Karlebo and/or at Hørsholm.

For further information please write or phone to Mr. Aage Nyholm Thomsen, Managing Director of Chr. Hansen's Bio Systems A/S, 10-12 Bøge Allé, DK-2970 Hørsholm, phone 02 76 66 66, ext. 4107.

Applicants should send a curriculum vitae to the Personnel Department, Chr. Hansen's Laboratorium A/S, 10-12 Bøge Allé, DK-2970 Hørsholm.

**CHR. HANSEN'S bio  
systems**

Chr. Hansen Bio System A/S is a subsidiary of Chr. Hansen's Laboratorium A/S, which is a Danish, internationally working group with more than 900 employees. For more than 100 years Chr. Hansen's Laboratorium A/S has sold special products and ingredients to the food industry. Chr. Hansen Bio System A/S is involved in marketing of biological products to improve the productivity within the agriculture sector.

**KLINIKUM DER  
ALBERT-LUDWIGS-  
UNIVERSITÄT FREIBURG**

Applications are invited for the position of an

## independent university assistant (C1)

at the Institute for Biology III (Dept. Genetics), starting October 1989 (approx. for 5 years).

The candidate is expected to head a small research group and has the possibility for habilitation. His research should center around molecular problems in cell, developmental, or tumour biology.

Applications incl. CV, list of publications, research proposal and two letters of reference, at the latest March 31, to Prof. A.E. Sippel, ZMBH, INF 282, D-6900 Heidelberg, FRG. (W5926)A

**MRC**  
Medical Research Council

## MEDICAL RESEARCH COUNCIL NATIONAL INSTITUTE FOR MEDICAL RESEARCH IMMUNOLOGY DIVISION

Applications are invited for a three year postdoctoral position in the Division of Immunology on control of B cell activation, proliferation and differentiation. The work will involve biological biochemical and molecular biological approaches. Previous relevant experience, although advantageous, is not essential.

Salary will be in the range £12,520 – £15,950 inclusive of London Allowance per annum.

Please send applications, including covering letter and full CV together with the names of two referees, to **Mr C R Russell, Administrative Manager, NIMR, The Ridgeway, Mill Hill, London, NW7 1AA. Closing date for this post will be 24 March 1989. Please quote job reference: 0521/II.**

The MRC is an Equal Opportunities Employer. (8584)A

## MASSEY UNIVERSITY

Palmerston North, New Zealand

### DIRECTOR, IMAGE ANALYSIS UNIT

Applications are invited from both men and women for the above appointment which includes half-time lecturing in the Department of Physics and Biophysics. The Unit undertakes fundamental research into image analysis methodology and provides a client advisory service. The appointment is for an initial period of three years.

The appointee would be expected to contribute to Electronics teaching in the Department of Physics and Biophysics. A practical knowledge and experience of DEC's VMS operating system, PC-DOS for the IBM-PC AT, "C" programming language and of general image analysis methodology is required. An ability to interact well with users is essential. Previous relevant management experience would be an advantage.

Salary is in the range NZ\$35,000 to NZ\$42,500 pa

Further information is available from Professor P T Callaghan, Head of Department of Physics/Biophysics (PN 69 099 extn 8364) and Professor D A D Parry, Chairman, Image Analysis Advisory Committee (extn 7473).

Applications including the names and addresses of three referees who may be contacted should be forwarded to Mrs V B Bretherton, Personnel Section, Massey University, Palmerston North, New Zealand, before 30 April 1989. Applicants resident in the UK should also send a copy to Appointments (36039), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF, from whom further information is also available.

(W5912)A

## UNIVERSITY OF EDINBURGH

### POSTDOCTORAL RESEARCH FELLOW (BIOCHEMISTRY)

#### DEPARTMENT OF VETERINARY CLINICAL STUDIES

Applications are invited for a three-year, extramurally funded research post involving mast cell proteinases, their isolation, characterisation and functional properties.

The post is available from 1st April 1989. Salary will be on the Research 1A scale (£9,865-£11,680) with placement according to age, qualifications and experience.

Further particulars may be obtained from the **Personnel Office, University of Edinburgh, 63 South Bridge, Edinburgh EH1 1LS**, with whom applications, including a curriculum vitae and the names and addresses of two referees, should be lodged not later than 22 March 1989.

Please quote reference no. 5630. (8576)A

## POSTDOCTORAL POSITION

available to study the biological and biochemical consequences of enhanced oncogene expression in human neuroblastoma cells. Project involves purification and characterization of autocrine growth factors. Experience in peptide biochemistry and/or molecular biology of preferred. Position is paid according to BAT IIa (DM 74,000/£22,000 p.a.).

Applicants should send a CV, including publications and the names of two referees to **Dr. Lothar Schweigerer, Dept. of Hematology/Oncology, Children's Hospital, University of Heidelberg, INF 150, 6900 Heidelberg, FRG.** (W5928)A

# Molecular Graphics

## Up to £23,000

The Sunbury Research Centre enjoys a worldwide reputation for technical excellence and provides a stimulating environment for ambitious research professionals. Our scientists and engineers enjoy the facilities of one of the most advanced and best equipped research establishments in Europe.

The BP Group has extensive interests in developing new materials for applications areas, including polymer composites, membranes, speciality chemicals and catalysts where molecular graphics and computer modelling techniques are playing a fundamental role in focused research. This has created challenging opportunities for exceptional applications-orientated chemists to research into the structure/property relationships of molecules and materials.

You will have a good honours degree and PhD in Chemistry, Chemical Physics or Material Sciences with a sound theoretical knowledge of polymer physics or chemistry. Exposure to computational techniques, theoretical chemistry and chemical crystallography would be desirable.

In addition to excellent career prospects you can expect an attractive salary and first-class benefits package.

**Please telephone or write for an application form, quoting ref P206/1/N to: The Recruitment Officer, BP Research, Sunbury Research Centre, Chertsey Road, Sunbury-on-Thames, Middlesex TW16 7LN. Tel: 0932 762028.**

#### NOTTINGHAM HEALTH AUTHORITY CITY HOSPITAL

#### PRINCIPAL MOLECULAR GENETICIST

The Trent Sub-Regional Genetic Service based in the above hospital, has a vacancy for an experienced Molecular Geneticist at Principal Grade to help provide and develop laboratory support for this established clinical specialty serving 1.5 million population. There is a second senior molecular geneticist in post. A Professor of Medical Genetics is to be appointed to direct the medical genetics service with its integrated molecular and cytogenetic laboratories during 1989, to be followed by the appointment of a Senior Lecturer in Molecular Genetics early in 1990.

For further information contact Dr J S Fitzsimmons, Consultant Clinical Geneticist, tel: (0602) 691169, ext 2944.

Salary: £15,180 to £20,989 p.a.

Application form and job description from the Personnel Department, Unit Headquarters, City Hospital, Hucknall Road, Nottingham NG5 1PB Tel: 625459 (24 hour answering service).

Closing date: 17th March 1989.  
(8553)A

#### University of Nottingham MEDICAL SCHOOL LECTURESHIPS IN BIOCHEMISTRY

Applications are invited for two posts of Lecturer in the modern well-equipped Department of Biochemistry located in The Queen's Medical Centre, Nottingham. The Department is responsible for teaching Biochemistry to medical and science students to honours level. Candidates should provide evidence of an active research interest in biochemical aspects of mammalian biology or medicine including in the case of one of the posts experience in cell biological or molecular biological techniques.

Salary will depend on the non-clinical Lecturer scale and the appointment will carry membership of USS. The initial salary will depend on qualifications, age and experience.

Professor F W Hemming will be pleased to answer telephone enquiries about the appointments (tel: 0602 421421 ext. 3619).

Other particulars and a form of application may be obtained from the **Deputy Registrar and Secretary, Medical School, Queen's Medical Centre, Nottingham NG7 2UH to whom completed applications should be returned by 31 March 1989.**

(8557)A

#### University of Bristol New Academic Appointment Scheme Department of Zoology

#### Lectureship in Behavioural and/or Population Ecology

This appointment forms part of an expansion of behavioural and population ecology in the Department. The successful candidate will, while developing his/her own interests, be expected to establish collaborative links with our research groups working in fields ranging from mammalian and avian to estuarine and fish ecology, and to take part in an expanded teaching programme in behavioural and population ecology. The post will attract substantial setting up funds.

Salary will be assessed in the Lecturer Grade A scale £9,260-£14,500 per annum.

For further details telephone Bristol 303136 (ansaphone after 5pm) or write to the **Personnel Office, Senate House, Bristol BS8 1TH.** Please quote reference JPB31.

Closing date 20 March 1989.

*An Equal Opportunities Employer*

#### UNIVERSITY OF CAMBRIDGE

#### University Lecturer in the Department of Anatomy

Applications are invited from suitably qualified graduates, including applicants from abroad, for the post of a University Lecturer in the Department of Anatomy to hold office from 1 October 1989 or as soon thereafter as possible. The Department has extensive and well-funded facilities for research, in various branches of neuroscience including brain research, neuroendocrinology and behavioural studies, molecular, cellular and developmental biology.

Salary range: £13,365 to £20,616.

Further information and application form from **The Secretary, Appointments Committee, 19 Trumpington Street, Cambridge, CB2 1QA** (Tel: 0223 33499 Fax: 0223 332355).

Closing date: 8 April 1989.

(8601)A

# UNIVERSITY OF OXFORD

## DEPARTMENT OF PLANT SCIENCES SIBTHORPIAN PROFESSORSHIP OF RURAL ECONOMY (PLANT SCIENCE)

The electors intend to proceed to an election to the Sibthorpian Professorship of Rural Economy (Plant Science) from 1 October 1989 or such later date as may be arranged. On appointment the professor will be required to assume the duties of Head of the Department of Plant Sciences not later than 1 October 1991. The stipend of the professor is at present £26,905 a year. There will also be pensionable allowance, currently £3,585, as head of department.

**Applications (eight copies or one from overseas candidates), naming three referees, but without testimonials, should be received not later than 13 March 1989 by the Registrar, University Offices, Wellington Square, Oxford OX1 2JD, from whom further particulars may be obtained.**

## University Lectureship in Metamorphic Petrology in association with St. Cross College

Applications are invited for a lectureship, to be filled from 1st October 1989 or as soon as possible thereafter, within the field of metamorphic petrology. The lecturer will be responsible for teaching metamorphic petrology, and may have research interests in any area within this subject. Stipend will be according to age on the scale £9,865 to £20,615 p.a., together with membership of the University's Superannuation Scheme. The lectureship, open to men and women, will be held in conjunction with an Official Fellowship at St. Cross College.

Further particulars may be obtained from Professor J. F. Dewey, Department of Earth Sciences, Parks Road, Oxford OX1 3PR to whom application (four copies, or one in the case of overseas applicants) including curriculum vitae, a statement of experience and research interests, a list of publications, and the names and addresses of three referees should be sent so as to arrive before March 30th 1989.

## OXFORD CENTRE FOR MOLECULAR SCIENCES Postdoctoral Research Assistant Time resolved studies on enzyme catalysis

The research assistant will work jointly with Dr. J. Hajdu, Dr. L. N. Johnson and Dr. A. J. Pratt on the application of Laue diffraction methods for the study of reaction mechanisms in enzyme crystals. In the first instance, the work will relate to glycogen phosphorylase and the design of suitable caged substrates in order to achieve synchronisation of the start of reaction with the start of data collection.

The post is tenable for 2 years initially, with the possibility of extension, on the Scale RS1A £9865-£12760 (according to age and experience).

**Applications in writing with full CV and 2 referees should be made to The Administrator, Oxford Centre for Molecular Sciences, c/o Dyson Perrins Laboratory, South Parks Road, Oxford, OX1 3QY, from whom further details of the post can be obtained.**

Closing date: 24 March 1989.

(8594)A

*The University is an Equal Opportunity Employer*

## UNIVERSITY COLLEGE LONDON LECTURER IN CHEMISTRY

Applications are invited for a Lectureship in the Department of Chemistry from 1 October 1989. Candidates should have special interests in the teaching of physical chemistry and in research in some area of physical chemistry. It is expected that the appointment will be made within the lower part of the Lecturer salary scale (£9,260 to £14,500 plus £1650 London Allowance).

Further particulars can be obtained from the **Head of the Department of Chemistry University College London, 20 Gordon Street, London WC1H 0AJ or telephone 01-387 7050 ext. 7451.** Applications (6 copies if possible) should reach him on or before 7 April 1989. *Equal Opportunities Employer.*

(8567)A

University of London  
BRITISH POSTGRADUATE MEDICAL FEDERATION

INSTITUTE OF DENTAL SURGERY

## Chair of Oral Biology

The Senate invite applications for the newly-established Chair of Oral Biology. The successful applicant will head the newly formed department which, with reorganisation of the research of the institute, will include a substantial proportion of existing biological work.

The major remit of the Professor will be to initiate an innovative programme of biological research, making best use of the excellent facilities of the Institute and associated Eastman Dental Hospital, and linking as appropriate with other science groups within and outside the BPMF. The Institute has a strong educational programme in which the staff of the department would be expected to participate.

The Institute, which has a particular interest in connective tissue research, wishes to strengthen work in basic science with particular emphasis on cell and molecular biology.

Applications (11 copies) should be submitted to the Teachers' Section (N), University of London, Senate House, Malet Street, London WC1E 7HU, from whom further particulars should first be obtained.

The closing date for receipt of applications is 10 April 1989.

## POSTDOCTORAL ASSOCIATE

Position available immediately in the area of peptide synthesis related to the development of novel AIDS vaccines. Position requires individual to participate in the design and synthesis of peptides which mimic anti-receptor antibody variable region structures to be used for the induction of anti-HIV responses in animals. This position is under the direction of Dr. Patrick Kanda, within our Department of Virology and Immunology. Southwest Foundation is a private non-profit institution funded, in part, by NIH. Annual postdoctoral salaries range upward from \$21,070, with consideration for prior, relevant postdoctoral experience. Applicants should have a background in biochemistry and/or organic chemistry or related area, with an interest in immunology.

Please send curriculum vitae and names and telephone numbers of three references to **Personnel Director (888), Southwest Foundation for Biomedical Research, P.O. Box 28147, San Antonio, Texas 78284.**

*Equal opportunity employer m/f.*

(NW3348)A

## ASSISTANT PROFESSOR THE UNIVERSITY OF WISCONSIN - MADISON

The School of Pharmacy at the University of Wisconsin - Madison invites applications for a full-time tenure-track position at the assistant professor level in the area of pharmaceuticals. Candidates should be capable of developing an independent, aggressive, and fundamental program of research on some aspect of the physical chemistry of biomolecules (preferably macromolecules). The primary interest should be in generating new knowledge at the molecular level, though the research should have potential application to drugs. Candidates should hold the Ph.D. in physical, analytical, or biophysical chemistry or in pharmaceuticals, and have relevant postdoctoral research experience. Teaching responsibilities will include undergraduate and graduate courses. Please send curriculum vitae with a description of research interests and names of three references by 1 April 1989 to: **Dr. Kenneth A. Connors, School of Pharmacy, University of Wisconsin, Madison, WI 53706; telephone: 608-262-2990.**

*The University of Wisconsin is an Equal Opportunity/Affirmative Action Employer.*

(NW3393)A

## UNIVERSITY OF GLASGOW DEPARTMENT OF NEUROLOGY

### Postdoctoral Research Fellow—Immunology

Postdoctoral research fellow with extensive experience in cellular immunology required to join newly formed large research group in neurobiology. The main interest of the group is in the altered responses to viruses in post-viral neurological diseases. Salary within £9,865-£15,720 p.a. on Research and Analogous Staff 1A scale. Post available for up to 5 years.

### Two Research Assistants in neurobiology-immunology

Positions available for immunologist-cell biologists to join research group studying effects of testosterone on immune system and on neuronal migration. Positions funded by N.I.H. and suitable for obtaining Ph.D. Salary within £8,675-£11,680 p.a. on Research and Analogous Staff 1B scale. Posts available for up to 3 years.

**Applications, including C.V., should be sent to Dr. Peter Behan, University Department of Neurology, Southern General Hospital, Glasgow, G51 4TF.**

(8558)A

## UNIVERSITY OF BRISTOL Electron Microprobe Operator in Microanalysis of Geological Materials

An Electron Microprobe Operator is required in the Department of Geology to oversee the establishment and operation of an electron microprobe laboratory. Experience in the microanalysis of silicate materials is essential. Preference will be given to individuals with knowledge and interest in electronics. Duties may also include development and maintenance of other electronic equipment.

The commencing salary will be at an appropriate point according to age, qualifications and experience on the Scale £12,150-£15,720 per annum.

The University does not issue application forms. Application should be made by letter including the names and addresses of three referees, and should be accompanied by a full curriculum vitae. Applications should be sent to arrive not later than 20 March 1989 to the **Registrar, University of Bristol, Senate House, Tyndall Avenue, Bristol BS8 1TH**, quoting reference JPB/35, from whom further particulars may be obtained.

## ***On The Leading Edge Of Clinical Cancer Research***

The Ontario Cancer Institute is Canada's largest centre for cancer treatment, research and education. The care, vision and professional collaboration of our people have earned us an international reputation for excellence.

We wish to appoint a **CHIEF RESEARCH OFFICER** to lead our highly-motivated research divisions.

The senior scientist who is appointed to this new position will have qualifications which include either a Ph.D, an M.D. or equivalent and accomplishments which would justify an appointment at the full professor level. We are seeking a person who has demonstrated significant skills in leading a team of senior investigators, working within a peer-reviewed, grant-supported environment.

Responsibilities will include leadership to a large group of independent scientists; collaboration with clinical departments to foster patient-related research; liaison with external bodies in government, universities and industry; and planning and priority-setting for research programs. A major challenge/opportunity will be to prepare for OCI's move to new expanded facilities within five years.

Canadian citizens will be given priority consideration. Scientists attracted by this important and challenging opportunity should submit appropriate documentation by May 1, 1989 to:

**Dr. D.R. Carlow, CEO and Chair of Search Committee**  
The Ontario Cancer Institute, 500 Sherbourne Street  
Toronto, Ontario M4X 1K9  
Telephone: (416) 926-4671 Fax: (416) 926-6545

**THE ONTARIO  
CANCER INSTITUTE**

(NW3395)A

## **RESEARCH SCIENTIST MOLECULAR BIOLOGIST: MOLECULAR GENETICIST**

A six-year tenure track position is available in the ICRF Laboratory of Molecular Pharmacology in Edinburgh. The overall aims of the group are to understand the factors which determine individual susceptibility to cancer as well as molecular mechanisms of tumour cell resistance to cytotoxic drugs. Candidates should have a strong background in eukaryotic or prokaryotic molecular biology and/or muscular genetics and will be expected to work independently on themes complementary to the main aims of the group.

The ICRF group is situated in the University of Edinburgh Department of Biochemistry and works closely together with other Departments in the University. The successful candidate will be considered for an honorary position within the University.

Salary range: £14,500-£23,000

For further information contact Dr. C. R. Wolf, I.C.R.F. Lab of Molecular Pharmacology, Hugh Robson Building, George Sq., Edinburgh EH8 9XD, U.K. Tel: 031-668-3343.

**Applications should be made by sending a full curriculum vitae together with the names and addresses of three referees to the Recruitment Officer, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX quoting reference 78/R.**

Closing date for applications: 21st April 1989

Smoking is actively discouraged.

**I M P E R I A L  
CANCER RESEARCH FUND**

## **RESEARCH ASSOCIATES**

**COR Therapeutics, Inc.** is a recently established and rapidly growing biotechnology company located in the San Francisco Bay Area. We specialize in the development of novel therapeutics for cardiovascular disease. We are actively recruiting highly qualified research associates to join our Research and Development Departments.

Research Associates are sought in Molecular Biology, Protein Biochemistry, Cell Biology, and Monoclonal Antibody Production.

These positions offer the opportunity to study basic mechanisms of receptor ligand interactions and to use this information to design therapeutic agents effective in the treatment of several types of cardiovascular disease. Preference will be given to individuals with prior research and/or laboratory experience.

**COR Therapeutics, Inc.** offers competitive salaries, benefits and attractive equity positions to its employees combined with the challenge and opportunity to make a significant contribution to this new organization. To apply, please send *curriculum vitae* to COR Therapeutics, Inc., 256 E. Grand Avenue, Suite 80, South San Francisco, CA 94080, ATTN: Human Resources. EOE

(NW3406)A

**COR Therapeutics, Inc.**

**UNIVERSITY OF CAMBRIDGE  
DEPARTMENT OF PATHOLOGY  
RESEARCH ASSISTANT/  
ASSOCIATE**

Applications are invited from post-doctoral scientists with experience in human cellular immunology. The position, which is available immediately and is funded for 2 1/2 years in the first instance, will involve studies on the regulation of immune responses in patients with schistosomiasis. Part of the work will be carried out in a large, multidisciplinary group in Cambridge: the successful applicant will also be expected to spend 3 to 4 months each year working in Kenya.

Salary up to £14,500, depending on age and experience plus travel and per diem expenses. Applications, with curricula vitae and the names of two referees, should be sent to: **The Superintendent, Department of Pathology, Tennis Court Road, Cambridge CB2 1QP.** For informal enquiries, please contact Dr. A.E. Butterworth at the same address (telephone 0223-353492) after 20th March. (8539)A

## **Research Scientist**

### **London Medical Hospital Medical College**

Applications are invited from cell/molecular biologists for a 6-year position within the ICRF Skin Cancer Laboratory (Head: Dr Irene Leigh) at the London Hospital Medical College. The Current interests of the group are in keratinocyte differentiation *in vivo* and *in vitro*, and melanoma. The person appointed would be expected to develop a research programme with complementary interests.

The group has close links with the mucocutaneous biology group, other cancer research groups at LHMC and the epithelial biology laboratories at ICRF.

Salary range: £17,000-£25,000.

For further details contact Dr. I. Leigh, London Hospital, London E1 (01-377-7749) or Dr. M. Swain, ICRF (01-242-0200).

**Applications comprising a full cv and names and addresses of three referees should be sent to: The Recruitment Officer, Imperial Cancer Research Fund, PO Box 123, Lincoln's Inn Fields, London WC2A 3PX quoting reference 89/R.**

Closing date for applications: 5th May 1989.

(8617)A

## **I M P E R I A L CANCER RESEARCH FUND**

### **MEDICAL RESEARCH COUNCIL TOXICOLOGY UNIT**

#### **MOLECULAR OR CELL BIOLOGIST**

Applications are invited for an MRC/ICI funded post-doctoral short-term non-clinical scientific post tenable in this unit for two years (with the possibility of extension to three years).

The project involves the separation of preneoplastic cells induced by genotoxic and neo-genotoxic carcinogens using flow cytometry and elutriation and probing the separated cells for altered phenotype including oncogene expression.

Remuneration will be at an appropriate point on the scales for university non-clinical academic staff. Further information may be obtained from **The Administrative Officer, MRC Laboratories, Woodmansterne Road, Carshalton, Surrey SM5 4EF (Tel. 01-643 8000)** to whom applications, including a full CV and the names of two professional referees, should be sent by **23 March 1989.**

The Council is an equal opportunity employer.

## **SENIOR POSTDOCTORAL RESEARCHER**

A position is available under the Wolfson Research Awards Scheme to work on the development of 2-dimensional dielectric spectroscopy. The successful candidate would have an interest and experience in interdisciplinary problems and in the programming and use of Personal Computers. In the first instance, the project would involve the construction and adaptation of appropriate software for obtaining and manipulating 2-D dielectric spectra. This would be the world's first such system. Subsequently the system would be used for the characterization of a variety of specific proteins and microorganisms, and the use of such a system as a generic biosensor (see Kell, D. B. *in* Biosensors — fundamentals and applications, ed. A. P. F. Turner, I. Karube & G. S. Wilson, OUP, 1987, pp. 427-468).

This post is available for 3 years at a point up to SCP8 (£13,870 p.a.) on the PDRA 1A scale (£9,865-15,720 p.a.). There is no specific closing date for this post, but suitably qualified candidates are urged to make their interest and availability known as soon as possible.

Application forms and further particulars from the **Staffing Officer, The University College of Wales, Old College, King Street, Aberystwyth SY23 2AX (Tel 0970 623177 Ext 207) — fax 0970 611446.** Informal inquiries in confidence to Dr D B Kell on 0970 623111 Ext 3055, 0970 617172 (fax) or via BITNET (DBK@UK.AC.ABERYSTWYTH.) (8572)A

### **DIRECTOR MOLECULAR GENETICS DIVISION**

Children's Hospital National Medical Center of Washington, D.C. is seeking an individual to direct a newly created Molecular Genetics Division in the Department of Clinical Genetics. Candidates must have an M.D., Ph.D or M.D./Ph.D. degrees and have previously demonstrated skill in the field of molecular genetics. The ability to supervise a rapidly growing research team and to conduct appropriate independent research is required.

Excellent salary and benefits package with tenured appointment at the Associate Professor or Professor level in the Department of Child Health and Development of George Washington University. Position available July 1, 1989. Send curriculum vitae and brief statement of research interests to:

**Kenneth N. Rosenbaum, M.D.**  
**Director, Clinical Genetics and Genetics Laboratory**  
**CHILDREN'S HOSPITAL**  
**NATIONAL MEDICAL CENTER**  
**111 Michigan Ave., N.W.**  
**Washington, DC 20010**

University of Edinburgh and  
Agricultural and Food Research  
Council Interdisciplinary Research  
Centre For Animal Genome  
Research

## DIRECTOR

Applications are invited for the post of Director of the Interdisciplinary Research Centre for Animal Genome Research. The Centre will be established by the University and the Research Council (AFRC) during 1989 and will be supported for an initial period of 10 years (subject to review after 4 and 8 years) by a substantial direct grant from the Council. Scientific review procedures and annual reporting will conform to AFRC norms.

The Centre will pursue a research programme in the field of genetic manipulation of vertebrate animals, including the production of transgenic animals by pronuclear microinjection, germline manipulation using embryonal stem cell techniques and genetic engineering of somatic cells by stemline repopulation, and it will also act as a focus for multidisciplinary interactive projects in mammalian biology, agriculture and medicine. It will have a core of scientific, technical and managerial staff. Designated academic staff on partial secondment from the University and elsewhere will assist and advise, and will carry out agreed programmes of research. It will accommodate visiting workers from University Departments, Research Councils and Charitable Institutes and Industry on a National and International basis, by agreement with the Director.

The Director will be a distinguished research worker in a field relevant to the programme of the Centre, and preferably will have a proven experience of management. He will be responsible for the efficient and cost-effective management of the Centre; recruitment and management of staff; scientific leadership and execution of an innovative research programme; promoting links with industrial, academic and other partners; obtaining additional financial support; dissemination of results and technology transfer. He will be employed by the University and appointed in consultation with the AFRC.

The salary will be within the professorial range. Further particulars may be obtained from the **Secretary to the University, University of Edinburgh, 63 South Bridge, Edinburgh, EH1 1LS, Scotland**, to whom applications (15 copies) including curriculum vitae and the names and addresses of three referees, should be lodged not later than 15th April 1989. Overseas candidates need submit only one copy of the application. Please quote reference no. 61/89.

DEPARTMENT OF BIOTECHNOLOGY

## RESEARCH ASSOCIATE (Fermentation Technology)

(Ref. 108)

Applications are invited from persons holding a PhD in Chemical Engineering or a related discipline for a 3 year post-doctoral position in the Department of Biotechnology. The appointee will be an ARC Research Associate on a project involving the design, operation and analysis of bench-scale fermentors for plant tissue and organ culture. Endowed with a high level of motivation, the successful applicant will be capable of working independently and skilled at finding innovative solutions to technical problems.

Experience with fermentation equipment and cell culture is required. A background which includes plant tissue culture studies would be advantageous, but is not essential. Commencing salary in the range \$A26,617, with possible progression to \$A30,360. Generous leave and study leave are also provided.

The position is full-time and available immediately.

Further information from Dr P. Doran on (02) 697 2086.

(W5933)A

Please submit written application, QUOTING REFERENCE NUMBER and including a complete resume and the names and addresses of three referees to: The Recruitment Officer, General Staff Office, P.O. Box 1, Kensington, N.S.W. 2033, Australia, by 17 March, 1989.

## ASSISTANT PROFESSOR OF TROPICAL PUBLIC HEALTH

The Department of Tropical Public Health at the Harvard School of Public Health is searching for an Assistant Professor with expertise in cellular biology and ultrastructure of parasites. The individual will interact with other members of a multidisciplinary department including immunologists, molecular biologists, vector biologists and epidemiologists, and be expected to develop a strong research and teaching program. Experience in immunology and/or molecular biology also preferred.

Applicants should send curriculum vitae including list of publications and reprints of representative recent publications to

**ad hoc Committee on Cellular Biology  
Harvard School of Public Health  
Department of Tropical Public Health  
665 Huntington Avenue  
Boston, MA 02115**

*The Harvard School of Public Health is an equal opportunity employer and applications from women and minority groups are encouraged.*

## RESEARCH ASSAY DEVELOPMENT

### SLOUGH

Celltech is one of Europe's foremost biotechnology companies; based at new purpose-built facilities in Slough, the company is already recognised as a world-leader in the bulk production of monoclonal antibodies and recombinant proteins for diagnostic and therapeutic use.

We are now looking for an experienced research scientist to join a group responsible for the design and development of antibody-based assays for contract research projects.

Qualified to PhD level, you must have up to three years' post-doctoral experience and a demonstrable interest in immunoassay development with enzyme-generated, fluorescent or electrochemical signal methods. You must have proven ability in the design and development of new assays. A knowledge of homogenous assays, automated assay systems, data analysis software

or monoclonal antibody derivation would be an advantage.

Working closely with project managers and commercial managers, you will also need highly developed analytical and communication skills.

Promotion prospects are excellent: Celltech values the contribution of research scientists and career development paths can take you to senior positions in scientific as well as managerial grades.

A highly competitive salary will be supported by a comprehensive benefits package which includes a pension scheme, free life assurance, discounted BUPA and relocation assistance if appropriate.

Please write with full details of your qualifications and experience to date to Mrs Jane Smith, BSc C BIOL MI BIOL, at Celltech Limited, 216 Bath Road, Slough, Berkshire SL1 4EN. Please quote Ref:173/C.

## Medical Affairs Officer

**T CELL SCIENCES, INC.**, is a health care company engaged in the development and marketing of therapeutic and diagnostic products. Positions at T CELL SCIENCES include a career-enhancing environment and offer the opportunity to interface with internationally recognized scientists in converting their discoveries into products.

We are seeking an experienced Medical Affairs Officer to participate in planning, conducting and evaluating a clinical trial program involving recombinant product(s) in potential therapies for myocardial injury and events involving tissue damages. Clinical trials for future products will include autoimmune diseases and certain cancers. The individual will be responsible for identifying and coordinating multicenter clinical trials; coordinating the development of clinical protocols; reviewing and interpreting all safety and efficacy issues of the therapeutic agents under evaluation; and preparing clinical study reports, IND updates and NDA submissions.

The successful candidate will have an M.D. degree (Board Certified in Internal Medicine) with additional training in one or more of the following disciplines: immunology, cardiology, infectious diseases and rheumatology; 3 or more years of pharmaceutical drug trial experience; knowledge of regulatory affairs; and exceptional organizational, communications and management skills.

Interested candidates please forward resume/C.V., salary requirements and description of career goals/publications or abstracts to Paula R. Freeman, T Cell Sciences, Inc., 38 Sidney St. Cambridge, MA 02139.

(NW3394)A

## CARDIOVASCULAR RESEARCH

**COR Therapeutics, Inc.** is a recently established and rapidly growing biotechnology company located in the San Francisco Bay Area. We specialize in the development of novel therapeutics for cardiovascular disease. We are actively recruiting a few highly qualified scientists with proven track records to join our Research Department. These scientists will join a research effort directed at the study of molecular mechanisms underlying various aspects of cardiovascular disease. The primary focus will be on growth factors and growth factor receptors, and receptors mediating vascular cell interactions.

### Molecular Biology

Expression of native, chimeric and mutant proteins. Experience with mammalian cell expression preferred. Objectives will be to use a molecular approach to understand protein function and to develop the use of expressed proteins as novel pharmaceutical agents.

**COR Therapeutics, Inc.** offers competitive salaries, benefits, and attractive equity positions to its employees combined with the challenge and opportunity to make a significant contribution to this new organization. To apply, please send *curriculum vitae* to COR Therapeutics, Inc., 256 E. Grand Avenue, Suite 80, South San Francisco, CA 94080, ATTN: Human Resources. EOE.

(NW3405)A

### Protein Biochemistry

Identification, isolation and characterization of structural and functional domains of ligands and receptors. Objectives will be to characterize structure-function relationships of these proteins and to use this information to develop receptor antagonists.

**COR Therapeutics, Inc.**

## ASSISTANT PROFESSOR OF TROPICAL PUBLIC HEALTH

The Department of Tropical Public Health at the Harvard School of Public Health is searching for an Assistant Professor with expertise in molecular biology, biochemistry or physiology or arthropods of medical importance. The candidate should have a record of productivity on the study of insects. The individual will interact with other members of a multi-disciplinary department including immunologists, molecular biologists, vector biologists and epidemiologists, and be expected to develop a strong research and teaching program.

Applicants should send curriculum vitae including list of publications and reprints of representative recent publications to:

## BIOLOGY EDITOR

The Guilford Press, a leading New York-based publisher in the behavioral sciences, is seeking a well-informed, enthusiastic, intellectually inquisitive person to develop a new program of books and journals in biology. The program will include molecular cell biology, genetics, biochemistry, neuroscience, immunology, pharmacology, and related domains.

This position provides an opportunity to work actively with prominent scholars. It is an ideal alternative for one wishing to leave academia, yet utilize his/her valuable training to advance the scientific enterprise. A graduate degree and some teaching experience are essential, unless the candidate has a strong publishing background in this field. Good writing and editing skills are a plus. The position entails extensive travel and attendance at major U.S. conferences.

To apply, please send resume and a covering letter (with salary requirements) to **Carolyn Graham, Guilford Publications, 72 Spring Street, New York, New York 10012.** (NW3399)A

**Department of Physiology  
UNIVERSITY COLLEGE LONDON**

## Appointment of three Lecturers

The vacancies arise as a consequence of appointments of members of staff to chairs elsewhere. The Department is responsible for teaching physiology to Medical and Science students. Our main research areas are Cell Physiology, Neurophysiology, Muscle (cardiac, smooth and skeletal) and Clinical Physiology. Applications are invited from active young research workers in these and in complementary fields of modern physiology. For one of the posts, we are seeking a scientist in the field of cellular and molecular aspects of endocrinology. Applications in the form of a curriculum vitae including research plans and the names and addresses of 2 referees should be sent to Professor R. Woledge, from whom further information can be obtained (01-380 7133), Department of Physiology, University College London, Gower Street, London WC1E 6BT by the 10th April 1989. Equal Opportunities Employer. (8469)A

## University of Reading

**Neuropsychopharmacology Lab.  
Department of Psychology**

## Postdoctoral Research Fellow and Postgraduate Research Assistant

required for a project focusing on drugs of abuse and the interaction between dopamine and opioid peptides. The FELLOW will use extracellular single unit recording and microiontophoretic techniques. Candidates should have a PhD in a neuroscience field; experience with electrophysiological techniques is not essential. The appointment is for 3 years; salary range £9,865-£11,070 p.a. The OFFICER will be involved in behavioural work relevant to the electrophysiological studies. The appointment is for 19 months at a salary of £8,675-£9,260 p.a. Applicants should possess a relevant first degree. Closing date for both positions is 30 March 1989. Informal enquiries to Dr David Clark on (0734) 318532. **Apply for Application Form** and further particulars to the Personnel Officer, University of Reading, Whiteknights House, P.O. Box 217, Reading, RG6 2AH, telephone (0734) 318754. Please quote ref. R8912. (8578)A

Still first with the best  
in science

**THE UNIVERSITY OF LEEDS**  
DEPARTMENT OF PURE AND  
APPLIED BIOLOGY  
**TWO LECTURESHIPS IN  
BIOLOGY**

Applications are invited for two posts of Lecturer available from 1 October 1989.

The successful candidates will have demonstrated an ability to initiate and carry out high-quality innovative research in the following fields:

1. Vertebrate Zoology, especially bio-mechanics and/or behaviour of vertebrates (ref no: 56/25).
2. Plant Molecular Biology (ref no: 56/26).

It is intended that the new appointments should consolidate existing departmental strengths through both independent and collaborative research.

Salaries will be on the scale for Lecturers Grade A (£9260-£14500), according to qualifications and experience.

Application forms and further particulars can be obtained from and completed applications forwarded to, the Registrar, The University, Leeds LS2 9JT (tel (0532) 333963 — direct line) quoting appropriate reference No. Closing date for applications 23 March 1989. (8593)A

**University of Nottingham**  
**Department of Physiology and  
Environmental Science**

Applications are invited for a Lecturer in Computer Modelling in Environmental Biology, commencing 1 September 1989. The ideal candidate will have research experience in the computer modelling of Biological systems and an interest in teaching statistics and computing to biologists.

Salary within the range £9,260 — £19,310 per annum depending upon age and experience.

Further details and application forms, returnable not later than 31 March 1989, from the **Personnel Officer, University of Nottingham, University Park, Nottingham NG7 2RD (Tel 0602 484848 ext 3355). Ref No 1225. (8555)A**

**ENVIRONMENTAL  
PATHOLOGY/TOXICOLOGY**  
NRSA-supported  
**PRE- AND POSTDOCTORAL  
POSITIONS**

available with research emphasis on cellular and molecular effects (mutagenesis, neurotoxicity, bio-transformation, DNA dosimetry) of toxic chemicals (especially trace metals, aromatic hydrocarbons, ozone respiratory epithelial injury, aflatoxins).

Inquiries: **Dr. N. K. Mottet, Program Director, Department of Pathology, SM-30, University of Washington, Seattle, WA 98195. U.S. citizen/permanent residents. An Equal Opportunity/Affirmative Action Employer. (NW3397)A**

**UNIVERSITY OF  
ZIMBABWE**

Applications are invited for the following posts:

**DEPARTMENT OF  
PHARMACY  
PROFESSORSHIP**

Applicants must have a first degree in Pharmacy (registrable in Zimbabwe) with appropriate higher degrees to the doctorate level, and extensive teaching, research and professional experience. The successful candidate will be required to undertake a major role in the continued development of undergraduate and postgraduate work in the Department and to conduct and lead appropriate research.

**ASSOCIATE  
PROFESSORSHIP/SENIOR  
LECTURESHIP/  
LECTURESHIP**

Applicants should be pharmacy graduates with appropriate post-graduate qualifications and clinical/hospital experience. The successful candidate will participate in the well developed teaching and research programmes in clinical pharmacy in the Faculty of Medicine. Pharm.D or ward pharmacist preferred.

*Salary Scales: Medicine/Veterinary (Including Professional Supplement) Lecturer: Z\$23,868-Z\$32,184; Senior Lecturer: Z\$33,132-Z\$35,172) Associate Professor: Z\$36,132-Z\$36,624; Professor: Z\$36,948 (fixed). Non Medical: Lecturer: Z\$19,860-Z\$28,176; Senior Lecturer: Z\$29,124-Z\$31,572; Associate Professor: Z\$32,532-Z\$33,624. Appointment on the above scales will be according to qualification and experience.*

**CONDITIONS OF SERVICE**

Both permanent and short-term contracts are offered. Persons who are not Zimbabwean citizens may be appointed only on a short-term contract basis for an initial period of two years. Short-term contracts may be extended. Applicants should quote reference number ASA/2/01/89 and submit six copies of applications giving full personal particulars which should include full name, place and date of birth, qualifications, employment and experience, present salary, date of availability, telephone number and names and addresses of three referees to the Deputy Registrar (Administration), University of Zimbabwe, P O Box MP 167, Mount Pleasant, Harare, Zimbabwe. Telegrams: UNIVERSITY; Telex 4-152 ZW. Applicants from outside Zimbabwe should also send a copy to the Appointments Officer, Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF, UK, from whom further details may be obtained.

Closing date for receipt of applications is 24 March 1989.

(W5935)A

**MEDICAL MOLECULAR BIOLOGY UNIT  
DEPARTMENT OF BIOCHEMISTRY  
UNIVERSITY COLLEGE AND MIDDLESEX SCHOOL  
OF MEDICINE**

Applications are invited for a postdoctoral position in the above unit supported by Action Research for the Crippled Child. The person appointed will undertake the cloning and characterization of the gene encoding a novel neuron-specific transcription factor which binds to the octamer motif in cellular genes and related TAATGARAT elements in herpes simplex virus immediate-early genes.

Post available from May 1st or thereafter by arrangement. Experience in either neurobiology, virology or molecular biology would be an advantage but not essential as training will be provided. Salary on RA1A scale from £11,680 to £15,720 depending on age and experience plus £1650 London Allowance.

Applications with cv and names of two referees or informal enquiries to Dr D S Latchman, Medical Molecular Biology Unit, Windeyer Building, Cleveland Street, London W1P 6B. Tel: 01-380 9343 or 01-636 8333 ext 3079.

Equal Opportunities Employer

(8566)A

**ROYAL POSTGRADUATE MEDICAL SCHOOL  
(University of London)**

**DEPARTMENT OF CHEMICAL PATHOLOGY  
RESEARCH ASSISTANT**

A graduate research assistant is required to investigate the involvement of the amylin gene in type II diabetes. Studies will include the identification of polymorphisms in the amylin gene for use in linkage analysis in type II diabetic families and the development of immunoassays for analysis of amylin gene expression. Although previous experience is desirable, training can be given to a suitably qualified candidate and the opportunity exists to register for a higher degree. The project is supported by a grant of 2 years duration from The British Diabetic Association.

Starting salary is up to £9413 (inc. London weighting) according to age and experience.

Application forms and further details are available from the **Personnel Office, Royal Postgraduate Medical School, 150 Ducane Road, London W12 0NN (tel: 01-740 3204) quoting ref: ACM7.**

Closing Date: 31 March 1989.

**UNIVERSITY OF BIRMINGHAM  
CRC — Department of Cancer Studies  
Research Fellow**

Applications invited for a post-doctoral research fellow to join a group of six working on (a) the role of specific chromosome translocations in leukaemogenesis in patients with ataxia telangiectasia (A-T), and (b) the location of the A-T gene. Experience in some recombinant DNA techniques is preferred. Those expecting to complete a PhD by October 1989 are also encouraged to apply.

Post for 3 years. Salary £9,865-£15,720 with superannuation. Maximum starting £11,680.

Informal enquiries to Dr A M R Taylor on 021-414-4471. Application forms and further particulars from **Senior Assistant Registrar, Medical School, Birmingham, B15 2TJ** to whom completed applications (3 copies) should be sent by 31st March 1989.

Quote Ref RF/CS/AMT.

ANEQUAL OPPORTUNITIES EMPLOYER.

**UNIVERSITY OF LIVERPOOL  
MAGNETIC RESONANCE RESEARCH CENTRE  
SENIOR DESIGN AND MAINTENANCE OFFICER**

To design, construct, test and maintain patient safety equipment, including such items as ECG Monitors, Defibrillators, Ventilators and, in addition, to carry out other electro-mechanical development projects such as the construction of the Radiofrequency antenna (coils) for Magnetic Resonance Imaging and Spectroscopy as well as other MR related projects.

The post requires previous experience in the design and maintenance of clinical equipment. It will involve working closely with the NHS on matters relating to patient safety. Familiarity with the relevant safety regulations will be essential. Candidates should be qualified to HNC level or equivalent, although a degree would be an advantage.

Salary within the range £9,277-£11,185 per annum (under review).

Quote Ref: PER/649/N.

Closing date: Friday, 17th March 1989.

*An Equal Opportunity Employer.*

Application forms available for the **Director of Staffing Services (NAS), The University, P.O. Box 147, Liverpool L69 3BX.** (8575)A

**THE INSTITUTE OF CANCER RESEARCH  
Fulham Road, London**

**A RESEARCH OFFICER** is required to work on a project that will be run jointly by Dr. B Reeves (Section of Pathology) and Dr. C.S. Cooper (Section of Chemical Carcinogenesis). This work will involve the identification of genetic changes that may be involved in the development of human soft tissue tumours and will require the use of several molecular genetic techniques including Southern analysis and production of genomic libraries. The post would be suitable for a science graduate with a particular interest in molecular biology or for someone with experience in molecular genetic techniques.

The salary depending on qualifications and experience is in the range £8321 to £11706 p.a. inclusive.

Applicants are advised that smoking is prohibited in the majority of the Institute's premises.

Applications should be sent, in duplicate, with the names and addresses of two referees to the **Personal Officer, Institute of Cancer Research, 17A Onslow Gardens, London SW7 3AL, quoting reference number 3.89.T.N.66** (8545)A

**SYNTHETIC PEPTIDE CHEMIST**

A private, non-profit research institute is seeking a peptide chemist to head up a small unit within a department to design and synthesize biologically active peptides, analogs and fragments for physiological studies and raising of antibodies. A strong background in organic synthesis is required and experience in solid phase peptide synthesis methodology is helpful but not essential. Initial salary, equipment and supplies will be provided with the understanding that the candidate is expected to participate with a group of biologists, biochemists and molecular biologists to secure funding from NIH to study the physiology of the polypeptide regulators in ovarian follicular fluid.

If interested, please send curriculum vitae, statement of research interest and names of at least three references to **Nicholas Ling, Ph.D., Head of Department of Molecular Endocrinology, The Whittier Institute for Diabetes and Endocrinology, 9894 Genesee Avenue, La Jolla, CA 92037.**

(NW 3398)A

**UNIVERSITY OF ULM**

**Position available**

**Molecular biology –  
regulation of hemopoiesis**

We offer a position for at least 3 years as a group-leader for a scientist with good background in molecular biology. Experimental hematology and stem cell research is well represented in our institute.

The applicant has the possibility to participate in the formulation of the research program that should address itself to the mechanisms of stem cell replication and differentiation.

Applications to **Prof. Dr. T. M. Fliedner, Institute of Occupational and Social Medicine, University of Ulm, Albert Einstein Allee 11 D – 7900 Ulm.** (W5930)A

**STUDENTSHIPS**

**FELLOWSHIPS IN  
JAPANESE NATIONAL  
LABORATORIES**

The Japanese Science and Technology Agency (STA), in association with the Royal Society, is offering postdoctoral fellowships of 6 to 24 months' duration tenable in Japanese national laboratories and public research corporations, to be taken up before the end of March 1990. Applications are invited from suitably qualified scientists and engineers under the age of 45, to research in any science or engineering discipline except military R&D. Fellowships include a return air fare, a monthly stipend, family allowance where necessary and health insurance. Provision for Japanese language training will also be made, but the working language for holders will normally be English. Successful candidates will subsequently be able to apply to the Royal Society for 'return-home' fellowships tenable in the UK.

Applications must be accompanied by a letter of invitation from the host institution and a clear research proposal. The Royal Society can provide on request information on the institutes in which the fellowships are tenable and advice on making initial contact. Those interested in applying should contact:

**The Executive Secretary (Ref: KK),  
The Royal Society,  
6 Carlton House Terrace,  
London SW1Y 5AG.  
Telephone: 01-839 5561 ext 309.**

CLOSING DATE FOR APPLICATIONS: 15 JUNE 1989. (8550)E

**THE ROYAL SOCIETY  
OF EDINBURGH**

**SUPPORT RESEARCH  
FELLOWSHIPS**

Applications are invited from Lecturers, aged under 45, holding permanent appointments for at least five years, in any Scottish University, Central Institution or College of Technology.

Support Fellowships enable temporary replacements to be appointed whilst the Research Fellows take study leave for twelve months, beginning 1st October 1989, to carry out advanced research in any discipline.

Application forms and further details are available from the **Executive Secretary, The Royal Society of Edinburgh, 22-24 George Street, Edinburgh EH2 2PQ,** and must be returned by 31st March 1989. (8596)E

## UNIVERSITY OF OXFORD

### NUFFIELD DEPARTMENT OF ANAESTHETICS and GREEN COLLEGE

#### POST DOCTORAL RESEARCH ASSISTANTSHIP (Respiratory Physiology) and

#### JUNIOR RESEARCH FELLOWSHIP, GREEN COLLEGE

Applications are invited from Physiologists with a PhD and experience in respiratory techniques, for a Wellcome Trust Post Doctoral Research Assistantship, to work with Dr C E W Hahn and Professor M K Sykes on the evaluation and development of a new technique for assessing cardio-respiratory function in the experimental laboratory and Intensive Care Unit. The project will involve microcomputer control of a system to deliver a sinusoidal inert gas forcing function to inspired air, and the subsequent analysis of the expired gases by mass spectrometry. Derived cardiopulmonary indices will be compared with those obtained by conventional techniques in the normal and sick lung.

The Applicant will be part of a team containing a medically qualified Research Fellow, a mathematician and technical support staff. A suitable applicant for this 3 year post may be offered a Junior Research Fellowship at Green College, for the grant duration. This will include membership of the Common Room, meals at Common Table and eligibility for membership of the Governing Body.

**Salary within range £9,865 – £13,870 on University Academic Related (1A) Scale.**

The post is available immediately, although the starting date is negotiable.

Informal enquiries and/or applications, including full CV and names of two referees, may be made to:

**Dr C E W Hahn, Nuffield Department of Anaesthetics, University of Oxford, Radcliffe Infirmary, OXFORD OX2 6HE. Tel: Oxford (0865) 727342 or 816779 (direct lines).**

*The University is an Equal Opportunity Employer.*

## ROCKEFELLER FOUNDATION BIOTECHNOLOGY CAREER FELLOWSHIPS

The Rockefeller Foundation announces a program of career development fellowships designed to enable scientists from developing countries, trained at outstanding centers for advanced research on biotechnology, to continue to work at those or other institutions for three months each year, over a period of at least three years, conducting advanced research and keeping abreast of new developments in their fields. The program will focus upon the development and application of advances in molecular and cellular biology and immunology relevant to agriculture, health, and reproductive biology.

Funding will be shared between the Foundation and the host laboratory, with the Foundation providing travel and per diem support. It is hoped that the fellowships will encourage the establishment of ongoing working relationships between outstanding younger scientists working at third world institutions, and research teams at advanced laboratories.

Applicants to this program should have at least Ph.D.- or M.D.-level training, a proven record of scientific productivity, and a permanent position at a research or teaching institution in their home country. A written project proposal must be developed and submitted jointly by the candidate and the laboratory sponsor.

Information about application procedures can be obtained by writing to **Biotechnology Career Fellowships, Fellowship Office, Rockefeller Foundation, 1133 Avenue of the Americas, New York, New York 10036, USA.**

(NW3382)E

## POSTDOCTORAL FELLOWSHIPS

The Imperial Cancer Research Fund is one of the largest independent cancer research institutes in Europe, employing approximately 400 scientists and clinicians. It has a wide ranging programme in fundamental, applied, and clinical cancer research.

### RESEARCH FELLOWSHIP IN CELL BIOLOGY

**£14,000 – £17,000**

Applications are invited for a post-doctoral fellowship, tenable for three years, to join a group working on the sorting of membranes during mitosis. These studies focus on the division of the Golgi apparatus and utilize a variety of techniques including immunoelectron microscopy, cell-free reconstitution and yeast molecular genetics. Preference will be given to applicants familiar with one or more of these techniques.

Further information can be obtained from Graham Warren, (01)-242-0200 Ext. 2281.

Closing date for applications: 28th April 1989. Ref: 79/R.

### RESEARCH FELLOWSHIPS IN GENETIC RECOMBINATION

**£13,300 – £16,000**

Applications are invited for two postdoctoral positions:

- (1) The mechanism of homologous pairing and strand exchange by the *E. coli* RecA protein
- (2) Resolution of recombination intermediates (Holliday junctions) in vitro.

Candidates for both positions should have experience in the techniques of molecular biology. Additional experience in cloning and gene manipulation would be advantageous for project (2). The fellowships are available at the ICRF's Clare Hall Laboratories situated 10 miles north of London and are tenable for a period of three years. Ref: 80/R.

**Applications, for any of the positions, comprising a full curriculum vitae and the names and addresses of three referees should be sent to the Recruitment Officer, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX quoting the appropriate reference. Smoking is actively discouraged** (8608)E

**I M P E R I A L  
CANCER RESEARCH FUND**

## EMBO

### EUROPEAN MOLECULAR BIOLOGY ORGANIZATION

#### SHORT TERM FELLOWSHIPS in molecular biology

The European Molecular Biology Organization awards, to scientists working in Europe and Israel in the field of molecular biology and allied disciplines, short term fellowships of one week up to three months duration. The fellowships are to support collaborative research between laboratories in different countries and provide a travel grant and subsistence allowance. Applications may be made at any time and are decided upon soon after the receipt of application.

Applications for exchanges between laboratories within any one country cannot be considered. Fellowships involving transatlantic travel are awarded only in exceptional circumstances. Inquiries should be accompanied by a self-addressed adhesive label.

Application forms and further details may be obtained from **Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 1022.40, F.R.G.** (W5706)E

## National Cancer Institute-Frederick Cancer Research Facility BIONETICS RESEARCH, INC.-BASIC RESEARCH PROGRAM POSTDOCTORAL FELLOWSHIPS

BRI-Basic Research Program Postdoctoral Fellowships are awarded for 1-2 years with stipends ranging from \$24,000 to \$30,000/year. The senior staff members and their research interests are

**George Vande Woude:** molecular basis of neoplastic transformation

**Stephen Hughes:** structure and function of HIV reverse transcriptase and integration protein; expression of cytoskeletal genes; retroviral vectors; transgenic birds

**George Pavlakis:** eukaryotic gene regulation; molecular mechanisms of cell transformation; molecular biology of HIV and pathogenesis of AIDS

**Peter Johnson:** mammalian transcription factors; molecular basis of tissue-specific gene expression

**Stephen Oroszlan:** immunochemistry and protein chemistry of retroviruses; structure and function of retroviral gene products; proteases

**Alan Rein:** retroviral genetics; functional analysis of retroviral genes using natural and synthetic mutants

**Nancy Rice:** molecular biology of retroviruses; oncogene expression

**William Lijinsky:** environmental carcinogenesis; mechanisms of carcinogenesis by nitrosamines and related compounds

**Anthony Dipple:** carcinogen-DNA interactions; polycyclic aromatic hydrocarbon carcinogenesis and mutagenesis

**Robert Moschel:** chemical synthesis of carcinogen-modified DNA; physical chemistry of carcinogen-DNA interactions; DNA adduct-induced mutagenesis in bacteria and mammalian cells

**Christopher Michejda:** biochemistry of carcinogen activation; DNA alkylation; chemotherapeutic agents

**Jeffrey Strathern:** cell type regulation; genome rearrangement, recombination, and DNA repair in yeast

Send a curriculum vitae and the names of three references to Dr. Maurice L. Guss, BRI-Basic Research Program, NCI-Frederick Cancer Research Facility, P.O. Box B (Rm 48), Frederick, Maryland 21701.

An equal opportunity/affirmative action employer M/F/H/V

**David Garfinkel:** molecular biology of the yeast retrotransposon Ty1; genome rearrangement and evolution

**Amar Klar:** gene regulation and homothallic mating-type switching in fission and budding yeast

**Stuart Austin:** chromosome stability in bacteria: regulation of plasmid replication and distribution of copies to daughter cells

**Richard Fishel:** molecular mechanisms and biochemistry of genetic recombination

**Donald Court:** regulation of gene expression by transcription initiation, transcription termination, and RNA processing

**Neal Copeland:** molecular genetics of murine leukemogenesis; developmental genetics; transposable elements and retroviruses

**Nancy Jenkins:** insertional mutagenesis by retroviral DNAs; transgenic mice; molecular biology of mouse development

**Luis Parada:** use of pluripotential stem cells to study molecular biology of development and the role of oncogenes; *in situ* hybridizations

**Peter Donovan:** development of the germ line; germ line mutations; cell matrix interactions

**Alexander Wlodawer:** structure of enzymes and oncogene products studied by X-ray diffraction

**Irene Weber:** crystallographic investigation of proteins, DNA, and protein-nucleic acid interactions

**J. Ronald Rubin:** crystallographic investigations of ligand-macromolecule interactions and drug-nucleic acid interactions

(NW3340)E

## CALIFORNIA INSTITUTE OF TECHNOLOGY THE MYRON A. BANTRELL POSTDOCTORATE FELLOWSHIP FOR SCIENTIFIC RESEARCH IN GEOLOGICAL AND PLANETARY RESEARCH

A fellowship will be awarded for postdoctoral studies in geological and planetary sciences at the California Institute of Technology. This fellowship carries an annual stipend of \$32,000 from Fall 1989, and in addition offers a research-expense fund of \$1,000 per year. The duration of the fellowship will normally be for 1 year. Applicants must be US citizens.

This fellowship program has been established to offer scientists, typically within two years of receipt of the Ph.D., the best possible opportunity to develop their talents. It is the intent of this program to identify and support innovative and creative work in the earth and planetary sciences, with particular emphasis on interdisciplinary work. In addition to individuals with degrees in geology, geophysics, geochemistry, or planetary science, we urge highly talented individuals with training in chemistry, physics, biology or computer sciences to apply. The Caltech faculty is currently active in Planetary Science, Geology, Geophysics, Geochemistry and Cosmochemistry.

Application forms may be obtained from **Professor G. J. Wasserburg, Chairman, Division of Geological and Planetary Sciences, 170-25, California Institute of Technology, Pasadena, California 91125.**

COMPLETED APPLICATIONS WITH REFERENCES  
SHOULD ARRIVE AT CALTECH  
BEFORE MAY 1, 1989.

Fellowship candidates will automatically be considered for other available post-doctoral positions at Caltech in their fields of interest.

*Caltech is an Affirmative Action/Equal Opportunity Employer. Women and minorities are encouraged to apply.*

(NW3377)E

## RESEARCH DEVELOPMENT AWARDS AT THE NATIONAL ZOOLOGICAL PARK

The National Zoological Park (NZP) is offering **Research Fellowships** for scientists to complete a major piece of work in their specialty, and to gain experience in research opportunities specific to zoological parks particularly in the areas of evolutionary biology, animal behavior, physiological zoology, ecology, sociobiology, reproductive physiology, conservation biology, and veterinary sciences. Applicants with a distinguished record of research contributions and those whose interests complement the NZP's current professional research staff are preferred.

Each award is for a maximum of 3 years; stipends to be commensurate with professional level and experience. Applicants must be at least 3 years post-doctorate. Timing and duration of the Fellowships are flexible, but the appointment must be activated within a year of the award and may not exceed a total of 36 months in duration (awards may be divided into several intervals, not less than 6 months each).

Field research is appropriate, however. Fellows are to be primarily based at the NZP to maximize interactions and collaborations with NZP staff. Individuals who have received support from or through the NZP for a significant period during the preceding 5 years are ineligible to apply.

For information contact: **Dr. Devra G. Kleiman, Assistant Director for Research, National Zoological Park, Washington, DC 20008.** Application deadline is 1 July 1989.

(NW3391)E

## Royal Postgraduate Medical School

(University of London)

### MRC/LRF LEUKAEMIA UNIT

# MRC

## Department of Haematology

One or two Research Fellowships to work in the above Unit have been made available through the generosity of the Hunting Gate organisation. The Unit has research programmes in the molecular and cell biology of leukaemia, and its primary objective is to improve the management of patients with leukaemia. Applications are invited from young investigators either medically qualified or with a Ph.D. who are interested in work on the molecular basis of leukaemia, and who have relevant research experience.

Additional details can be obtained and an informal meeting can be arranged with the Director Prof L. Luzzatto and members of the Unit by phoning 01-740 3234.

The appointment is for three years with salary on the University scale.

Applications, including cv, bibliography, statement of research interests and intentions and names of three scientific referees to the **Personnel Office, Royal Postgraduate Medical School, 150 Ducane Road, London W12 0NN** quoting ref: **HG/LRF.** (8586)E

## Postdoctoral Fellow Program

### Gene Expression in Plants

Applications are invited for Postdoctoral Fellowships to join a dynamic and ongoing basic research

program in plant molecular biology. Project includes the characterization of genes expressed in specific cells and tissues, and the study of promoter function.

Highly motivated individuals with a strong background in molecular biology should apply by sending a CV and the name of three references to: Calgene Fellow Program, 1920 Fifth Street, Davis, CA 95616. An equal opportunity employer.

# CALGENE

(NW3388)E

## THE MORRISON MEMORIAL POSTDOCTORAL FELLOWSHIP

The Department of Biochemistry, St. Jude Children's Research Hospital, is enlarging its research efforts in the area of the molecular and cellular biology of signal transduction. As part of this expansion, the Board of Governors has established a memorial fellowship in honor of Dr. Martin Morrison, the founding chairman of the Department. The research programs within the Department are well equipped and offer recent Ph.D. or M.D. graduates the opportunity to participate in energetic, multidisciplinary groups dealing with a range of basic and clinically oriented research. Current research programs within the Department include:

- W.Y. Cheung: Regulatory properties and biological functions of calmodulin;  $Ca^{2+}$  regulated enzymes.
- J. Cleveland: Growth factor regulation of gene transcription.
- V.A. Fried: The ubiquitin system and post-translational regulatory pathways.
- J.N. Ihle: Mechanisms of hematopoietic stem cell growth regulation, differentiation and transformation.
- S. Jackowski: Regulation of phospholipid metabolism and the production of lipid-derived second messengers.
- C. Rock: Hormone and growth factor stimulated phospholipase C.
- E. Thomas: Antimicrobial and antitumor mechanisms of leukocytes.

Applicants should submit a brief statement of their research interests, curriculum vitae, reprints and names of three references to:

**The Morrison Postdoctoral Fellowship  
Department of Biochemistry  
St. Jude Children's Research Hospital  
332 N. Lauderdale  
Memphis, TN 38101**

*An Equal Opportunity/Affirmative Action Employer*  
(NW3401)E

### INTERNATIONAL CANCER RESEARCH FELLOWSHIP

The Hayashibara Mutual Aid Fund, a non-profit making organization within the Hayashibara Group announces a fellowship program. Two awards will be made annually. Fellowship will be taken up at the newly opened Fujisaki Cell Center which is devoted for the basic and applied research related to the problems in human cancer. The fellowship is normally made for one year and is renewable for up to five years. The fellowship will be expected to commence within six months of the announcement of the awards. The awards are for high quality research work in one of the three categories described below.

1. Fundamental Leukemia-Lymphoma Research,
2. Cytokine-Lymphokine Research,
3. Hematopoietic Cell Cultures.

Qualified person who has a Ph.D., an M.D. or equivalent qualifications will be awarded on merit to suitably qualified research proposal and experiences. Additional information and application forms will be obtained from: **Jun Minowada, M.D., Director, Fujisaki Cell Center, 675-1, Fujisaki, Okayama 702, Japan.** (W5829)E

### Hebrew University Medical School

## POSTDOCTORAL FELLOWSHIPS

Available to study gene regulation and DNA replication in eukaryotes and prokaryotes in the laboratories of Howard Cedar, Aharon Razin and Gad Glaser. A background in Molecular Biology is required. Funding for 2-3 years.

Send C.V. and names of three references to **Dr. Howard Cedar, Dept. of Cellular Biochemistry, Hebrew University Medical School, P.O.B. 1172, Jerusalem. ISRAEL 91010.** (W5920)E

## PHARMACEUTICAL SCIENCES INSTITUTE RESEARCH COUNCIL STUDENTSHIPS AVAILABLE IN OCTOBER 1989

The Institute is actively involved in a broad drug research programme ranging from eukaryotic and prokaryotic cell biochemistry and biology, molecular pharmacology and toxicology, synthetic organic chemistry, X-ray crystallography and computer graphics to drug formulation, pharmacokinetics and clinical trials of drugs emanating from the Institute.

Research takes place in SIX research groups. The presence of 16 postdoctoral fellows, working in new well-equipped laboratories, facilitates an excellent environment for research training. Elements of formal training exist in some groups.

The present postgraduate population of 50 is divided between the following groups:

**Toxicology Group:** molecular toxicology of formamide and nitroalkane solvents; cellular ionic homeostasis; mechanisms of toxin-induced cell death.

(Group Convenor: Dr. Andreas Gescher)

**Microbiology Group:** influence of growth environment upon microbial pathogenicity and antibiotic sensitivity; chemical and immunochemical composition of the microbial surface.

(Group Convenor: Professor Michael Brown)

**Drug Development Group:** the design and synthesis of new drug entities for the treatment of AIDS; pro-drugs and soft-drugs; X-ray crystallography, computer graphics; topical delivery, drug encapsulation and controlled release formulations; drug targeting.

(Group Convenor: Professor Malcolm Stevens)

**Drug Mechanisms Group:** physiological and pharmacological determinants of vascular reactivity; receptor mechanisms; calcium homeostasis; ischaemic conditions; pharmacological mechanisms of anxiety and migraine.

(Group Convenor: Professor Brian Ferry)

**Cancer Research Campaign Experimental Chemotherapy Group:** colon and leukaemic tumour cell differentiation; the activation of stress genes in cell differentiation and death; tumour-host metabolism and cancer cachexia; membrane biochemistry and pharmacology, ion flux in mitogenesis; cellular and biochemical pharmacology of phorbol esters; synthesis of DNA-sequence specific agents, inhibitors of tyrosine protein kinases; drug metabolism of azido-containing drugs and imidazotetrazinones.

(Group Convenor: Dr. John Hickman)

**Pharmacy Practice Group:** Drug utilisation studies; research on the advisory role of the pharmacist; applications of information technology in pharmacy practice.

(Group Convenor: Mr. Michael Jepson)

At least TWELVE research training studentships will be available in October 1989. Candidates should have, or expect to obtain, a first or upper second class honours degree in pharmacy, the life or physical sciences.

For further details please write to the appropriate group convenor (see above), Pharmaceutical Sciences Institute, Aston University,

Birmingham B4 7ET, enclosing a full CV and the names of two referees.  
Closing date: 1st April, 1989.

(8610)F

### ASTON UNIVERSITY

#### UNIVERSITY OF READING

##### School of Animal and Microbial Sciences Department of Biochemistry & Physiology POSTGRADUATE STUDENTSHIP

Applications are invited for a postgraduate research studentship to study the control of gene expression in muscle in relation to animal growth. The successful applicant will join the Department's active Growth Biochemistry and Molecular Biology Groups and will receive an excellent training in the techniques of molecular biology as applied to animal science. The studentship is sponsored by the Ministry of Agriculture, Fisheries and Food.

Applicants should have or expect to obtain at least an upper second class degree in a relevant science subject. Applications, including a full curriculum vitae and the name and addresses of two academic referees should be sent to **Dr M. A. Lomax or Dr D. Savva, Department of Biochemistry & Physiology, University of Reading, Whiteknights, PO BOX 228, Reading RG6 2AJ (Tel. 0734 875123).** (8540)F

#### THE UNIVERSITY OF LEEDS

##### DEPARTMENT OF BIOCHEMISTRY STUDENTSHIPS IN PLANT BIOTECHNOLOGY

Two SERC studentships are available that have been 'ear-marked' for research projects in the laboratory of Dr. Dianna Bowles.

- (i) plant molecular biology: isolation and characterization of genes encoding proteins involved in cell signalling;
- (ii) plant molecular pathology: isolation and characterization of defence-related genes identified in resistance responses to nematodes.

Both projects will be carried out within a multi-disciplinary team combining expertise of cell biology, biochemistry and recombinant DNA techniques.

Applicants should have, or hope to gain shortly, a good first degree in Biochemistry, Molecular Biology or Plant Molecular Sciences.

Informal enquiries to **Dianna Bowles (0532-333125)** and written applications to the **Departmental Secretary, Department of Biochemistry, University of Leeds, LS2 9TJ.** (8592)F

## 1989 PHD OPPORTUNITIES

Celltech Limited is one of Europe's leading biotechnology companies. We operate from our excellent purpose-built facilities in Slough, and are among the leaders in the research and manufacture of protein-based drug products. We now invite applications for two:

### 3 YEAR RESEARCH STUDENTSHIPS for October 1989 in the following fields

- RO1) Isolation and analysis of abzymes using microbial secretion systems.**
- RO2) Culture of mammalian cell lines producing recombinant proteins.**
- RO3) Expression and characterisation of human immunodeficiency virus antigens.**
- RO4) Pharmacological control of inflammation using monoclonal antibodies to adhesion molecules.**
- RO5) Investigation of the reaction mechanisms of metalloproteinases, relevant to human connective tissue disorders.**

Applicants should have or expect to attain a First or Upper Second Class Honours degree in a relevant subject.

Please send a C.V. including the name of two referees, and indicate the research project(s) reference in which you are interested to: Jane Smith, Celltech Limited, 216 Bath Road, Slough, Berks. SL1 4EN. Closing date: 31.03.89 (8615)F

# CELLTECH

ASSISTANTSHIPS

### UNIVERSITY OF OXFORD Department of Experimental psychology

#### RESEARCH ASSISTANTSHIP(S) IN THE NEUROPHYSIOLOGY OF TASTE, VISION OR MEMORY

Applications are invited for post-doctoral or graduate positions to analyse the activity of single neurons in cortical taste and visual areas and limbic structures such as the hippocampus in the primate. Applications will be particularly welcome from scientists with interests in neurophysiology, information processing in the cerebral cortex, and/or mechanisms of learning and memory. The salaries are on the RS1A scale, £9,865-£15,720, or the RS1B scale £8,675-£13,365. Applications including the names of two referees, or enquiries, to Dr. E.T. Rolls, University of Oxford, Department of Experimental Psychology, South Parks Road, Oxford OX1 3UD. The University is an Equal Opportunities Employer (8579)P

### UNIVERSITY OF DUNDEE DEPARTMENT OF BIOLOGICAL SCIENCES POSTDOCTORAL ASSISTANT CYANOBACTERIAL TOXINS

Applications are invited from post-doctoral biologists, microbiologists, botanists and biochemists for a research assistantship to study cyanobacterial toxins, their persistence and removal from freshwaters. The appointee will join an established group studying the production, properties and actions of peptide and alkaloid toxins of the major freshwater bloom-forming cyanobacteria. The position is for TWO YEARS and is available immediately. Salary will be on the PDRA scale (£9,865 - £15,720), commensurate with age and experience. Applications with CV (2 copies) including the names and addresses of 2 referees to the Personnel Office, The University of Dundee, DD1 4HN, UK quoting ref. EST/405/89/N. Further information may be obtained by telephoning (0382) 23181 Ext. 4767. (8543)P

## BRITISH DIABETIC ASSOCIATION

### RESEARCH STUDENTSHIPS

Applications are invited for three studentships recently awarded by this Association. Applicants should be science graduates who possess, or expect to obtain a 1st class or Upper Second class honours degree. The studentships will be of three years duration and should lead to the successful candidate achieving a PhD. The annual maintenance grant will be £4500. All three studentships are available from 1st October 1989 and applications should be made to the respective Universities as detailed below by 3rd April 1989, enclosing a c.v. and the names of two academic referees.

1. UNIVERSITY OF BRISTOL. "Action of insulin on mRNA translation"  
This project will investigate the molecular mechanisms by which insulin stimulates protein synthesis. The successful applicant will receive training in a variety of techniques including the use of animal models, protein isolation, the assay of protein synthesis and the activity of translational components and protein and peptide analysis.  
Applications should be sent to Dr C Proud, Department of Biochemistry, School of Medical Sciences, University of Bristol, University Walk, Bristol BS8 1TD, U.K. Tel. 0272-303030
2. UNIVERSITY OF CAMBRIDGE. "Cellular regulation of proinsulin endopeptidases"  
This project aims to assess the importance of intra-compartmental pH and Ca in the regulation of the endopeptidases involved in proinsulin conversion to insulin in the pancreatic B-cell of normal and prediabetic animals. (Nature 333, 33, [1988]). The successful applicant will become well versed in protein purification methodology, molecular cloning techniques and the immunological approaches to study the biosynthesis, compartmentation and post-translational modification of proteins.  
Applications should be sent to Dr J C Hutton, Department of Clinical Biochemistry, Addenbrooke's Hospital, Hills Road, Cambridge, U.K. Tel. 0223-336790
3. UNIVERSITY OF OXFORD  
NUFFIELD DEPARTMENT OF SURGERY and the INSTITUTE OF MOLECULAR MEDICINE. "Immunoregulation of Type 1 Diabetes"  
The aim of this project is to present Type 1 diabetes in a murine model of the disease to investigate the role of Class II molecules in insulin dependent diabetes and to aim towards a rational approach for the prevention of the disease by manipulation of the pathways in which Class II molecules interact. The successful applicant will be trained in a variety of immunological and DNA techniques.  
Further details are available from Dr J Todd. Tel. 0865-817535. Applications should be sent to The Administrator, The Nuffield Department of Surgery, Level 6, John Radcliffe Hospital, Headington, Oxford OX3 9DU. Tel. 0865-64711 (8585)F

### CHRISTIE HOSPITAL AND HOLT RADIUM INSTITUTE RESEARCH ASSISTANT/RESEARCH STUDENT

A research assistantship (£10,000-14,000) and a Ph.D. studentship (MRC Scale) are available in the department of Tumour Biology. Applications are invited from candidates who have, or expect to obtain, first or upper second class degree and are highly motivated towards research. The successful applicants will join an active research group working on the control of blood vessel growth in tumours, wound healing and other pathological situations. Applications including a C.V. and the names of two referees should be sent to: Dr D C West, Clinical Research, Christie Hospital & Holt Radium Institute, Wilmslow Road, Withington, Manchester M20 9BX, England. (8598)P

### IMPERIAL COLLEGE (University of London) Blackett Laboratory

#### Postdoctoral Research Assistant

Applications are invited for a postdoctoral research assistantship to work on the interpretation of infrared spectra of Supernova 1987A. Using the Anglo-Australian Telescope, a body of very high quality spectra in the 1 to 4 micron region have been obtained and observations continue. These data are providing unique insights into the structure, composition and evolution of supernovae.

We seek a physicist/astronomer to develop late-time spectral models and to use the results of this work in conjunction with the infrared data to extract physical information about Supernova 1987A. Proven ability in working with astrophysical atomic/molecular spectra and/or radiative transfer processes is desirable.

The post is available for a period of up to three years. Salary is on the RA1A Scale in the range £11,515-£17,370 (including LW) depending on age and experience. Enquiries or applications (full CV and names and addresses of two referees) to Dr. W.P.S. Meikle, The Blackett Laboratory, Prince Consort Road, London SW7 2BZ (Tel. 01-589 5111 X6664).

Closing date for applications: 30 April 1989.

### MARINE BIOLOGICAL ASSOCIATION OF THE UNITED KINGDOM RESEARCH AWARDS

Applications are now invited for research awards to enable scientists from the United Kingdom or from abroad to work at the Association's Citadel Hill Laboratory, either as independent visitors or in collaboration with work currently being undertaken as part of the Association's Research Programme. Two levels of award are available:

**RESEARCH BURSARIES** available for visitors at all levels of experience from graduate students to senior scientists. Several awards are made each year with a maximum value of £2,500.

**RAY LANKESTER INVESTIGATORSHIP** available to postdoctoral research workers with several years of research experience in some aspect of marine biology or marine physiology. One award is made each year to a value of £5,000 to enable visitors to work at the Laboratory for a minimum of 5 months over an 18 month period.

Applications are invited for the 1989/90 Financial Year (1 April 1989 to 31 March 1990) with a closing date of 31 March 1989. Enquiries are also welcome for awards to be made in 1990/91. Successful applicants will be expected to become members of the Association.

Further details may be obtained from:

**Dr Gerald Boalch, The Bursar**  
**Marine Biological Association of the**  
**United Kingdom**  
**The Laboratory, Citadel Hill**  
**Plymouth, PL1 2PB, England**

### THE ANDERSON PRIZE FOR THE ENRICHMENT OF LABORATORY ANIMAL ENVIRONMENT

At the Silver Jubilee Meeting of the Laboratory Animal Science Association in September 1988, Professor R S Anderson of Liverpool University suggested that in order to encourage the continued improvement of laboratory animal welfare a prize should be given for the best paper published on the enrichment of the environment of animals used for scientific purposes. The Laboratory Animal Science Association and the St. Andrew Animal Fund are pleased to announce that they have jointly taken up this suggestion.

An Annual Open Prize of £750, the Anderson Prize, will be award-

ed for the best original published work which demonstrates a clear benefit to laboratory animals by enrichment of their environment.

The first award will be made for work which has been carried out in the United Kingdom and published during the period January 1st 1983 to December 31st 1988 in scientific or technical journals of any country of origin. Entries by the candidates themselves or by others acting on their behalf, together with four copies of the paper and its English translation if relevant, should be sent to The Anderson Prize, The Laboratory Animal Science Association, 20 Queensberry Place, London SW7 2DZ, so as to arrive not later than July 31st 1989. All entries will be acknowledged. The prize will be presented at the LASA meeting to be held at Solihull in October 1989. (8603)N

### ACCOMMODATION

#### Are you going to the University of Illinois?

Retired U of I professor will exchange house for one abroad for 1989/90. Write **Herbert Goldhor, 39 Maple Court, Champaign, IL 61821, USA.**

KREBS INSTITUTE FOR BIOMOLECULAR SCIENCES  
DEPARTMENT OF MOLECULAR BIOLOGY AND BIOTECHNOLOGY  
**Molecular Biology of Gene Expression**

Applications are invited for a SERC-funded

## Postdoctoral Research Assistantship

tenable for three years starting 1 May 1989 or thereafter.

The project involves biochemical and molecular-genetic studies on the structure, oxygen-sensing, and DNA-recognition of the anaerobic gene activator protein (FNR) of *E. coli*, and it is a joint project between Professor J R Guest and Dr P C Engel.

Applicants, preferably with experience in protein biochemistry or molecular biology should send CV and names of two referees to **Professor J R Guest, Department of Molecular Biology & Biotechnology, The University, Western Bank, Sheffield, S10 2TN** by Friday 23 March 1989, who will supply further details if needed. Starting salary will be up to point 7 on the scale for Research & Analogous Staff, Grade 1A (£9,865-£13,365 pa) depending upon age, and experience. Reference R865/N.

## COURSES & CONFERENCES & SYMPOSIA

### HARDEN CONFERENCE

#### 32nd: 'INOSITOL LIPIDS IN CELL FUNCTION'

Wye College, Ashford, Kent, 3-8 September 1989

Organizing Chairman: R. H. Michell (Birmingham)

Harden Lecturer: M. J. Berridge

*Principal Topics:* Receptor and G-protein coupling to phosphoinositidase C; Molecular Biology of phosphoinositidase C and protein kinase C; Calcium mobilisation and other functions of inositol phosphates; Relationship between inositol lipid signalling, cell proliferation and oncogenes; Inositol lipid glycans in protein anchoring and cell regulation.

*Conference Fee and Full Board (inc. VAT):* £250 for applications received by 1 June 1989, £300 for those received thereafter.

*Information:* The Meetings Officer, The Biochemical Society, 7, Warwick Court, London, WC1R 5DP, U.K. Tel: 01-242 1076, FAX: 01-831 1853. (8590)C

### IMPERIAL COLLEGE OF SCIENCE, TECHNOLOGY AND MEDICINE (University of London)

#### M.Sc. in Chemical Research

This one-year degree course provides training in modern research methods and includes an individual research project in a branch of chemistry. Applicants should hold (or expect to hold) a good honours degree in chemistry or a combined subject degree with chemistry as one component.

Further details and application forms may be obtained from the **Senior Assistant Registrar (Admissions), Imperial College, London SW7 2AZ.** (8587)C

### HARDEN CONFERENCE

#### 33rd: 'CELLULAR BARRIERS AND DRUG TARGETTING' Wye College, Ashford, Kent, 10-15 September 1989

Organizing Chairman: H. M. Patel (London)

Harden Lecturer: G. E. Palade

*Principal Topics:* Physiological and biochemical properties of cellular barriers; Anatomical and cellular considerations in drug targetting in liver and lung; Serum opsonins and Reticuloendothelial system; Drug carriers; Clinical trials with drug carriers; Specific delivery via nasal, gastrointestinal, systemic, transdermal, intracellular routes.

*Conference Fee and Full Board (inc. VAT):* £250 for applications received by 1 June 1989, £300 for those received thereafter.

*Information:* The Meetings Officer, The Biochemical Society, 7 Warwick Court, London, WC1R 5DP, U.K. Tel: 01-242 1076, FAX: 01-831 1853. (8591)C

## 1989 Short Course Programme

Wednesday 10-Friday 12 May

### Which Immunoassay?

Faced with an ever increasing range of methods for immunoassay, the busy laboratory scientist is often hard pressed to make a choice. By combining informative lectures and workshops, the participants will investigate RIA, IRMA, EIA and 'dedicated' systems, gaining hands-on experience on which to base an answer to "Which Immunoassay?"

Fee: £195.00

Monday 12-Friday 16 June

### The Intensive Radioimmunoassay Course

Once again, we are pleased to offer this popular and informative course covering all aspects of RIA and associated techniques, from first principles to latest developments in the field. An intensive course of lectures and practical exercises will ensure that participants have a thorough background of the technique.

Fee: £295.00

Wednesday 5-Friday 7 July

### Recombinant DNA Technology — A Refresher Course

Recombinant DNA technology is one of the areas of growth in modern research. By a combination of lectures and demonstrations, this course will update workers in the field, and keep them abreast of the latest developments.

Fee: £125.00

Monday 10-Friday 14 July

### Modern Techniques in Enzyme Immunoassay

Enzyme linked immunoassay is a widespread technique, and forms the basis of many commercially available analysis protocols. By combining lectures with a rigorous practical schedule, participants will investigate enzyme immunoassay techniques using model and real systems and evaluate many of the variants of the basic technique.

Fee: £295.00

Other course planned for later this year are

- Everyday Molecular Separation
- Modern Applications of UV/VIS Spectrophotometry

Further details on these courses may be obtained from:

FIRST ANNOUNCEMENT, CALL FOR POSTERS AND REGISTRATIONS

**FOURTH INTERNATIONAL  
CONFERENCE ON PROGRESS  
IN CANCER RESEARCH  
APRIL 30 – MAY 2, 1989  
SAN REMO, ITALY**

**Organized by:**

National Institute for Cancer Research – Genoa, Italy  
Italian League Against Cancer

**In collaboration with:**

Regione Liguria  
Faculty of Medicine University of Genoa, Italy  
Imperia Provincial Council, Italy  
The City Council of San Remo, Italy

**Scientific and Organizing Committee:**

Renato Dulbecco, U.S.A. (Chairman); Robert C. Gallo, U.S.A.;  
Lorenzo Moretta, Italy; Leonardo Santi, Italy; Inder M. Verma, U.S.A.

**General Secretary:**

Giovanni Lotti, Italy

**Conference topics will focus on:**

Oncogenes and Antioncogenes – Lymphocyte Subpopulations – Cell  
Signalling Lymphokines – Anti-Tumor Cytotoxicity – Immunotherapy  
of Cancer – AIDS and Cancer

**Invited participants include:**

Anton Berns, the Netherlands; Luigi Chieco-Bianchi, Italy; Giuseppe  
Della Porta, Italy; Renato Dulbecco, U.S.A.; Ronald M. Evans, U.S.A.;  
Manlio Ferrarini, Italy; Guido Forni, Italy; Luigi Frati, Italy; Robert C.  
Gallo, U.S.A.; Felice Gavosto, Italy; Thomas Graf, Germany; Carlo  
Grossi, Italy; Edward Harlow, U.S.A.; Michael Y. Hawkins, U.S.A.;  
Chris Y. Marshall, England; John D. Minna, U.S.A.; Malcolm A. S.  
Moore, U.S.A.; Alessandro Moretta, Italy; Lorenzo Moretta, Italy;  
Sergio Romagnani, Italy; Sandro Pontremoli, Italy; Elio G. Ronda-  
nelli, Italy; Gaetano Salvatore, Italy; Leonardo Santi, Italy; Jack L.  
Strominger, U.S.A.; Jean Paul Thiery, France; Giancarlo Vecchio,  
Italy; Inder M. Verma, U.S.A.; Carlo Zanussi, Italy; Luciano Zardi, Italy.

**Registration fee, including lunch, will be 400,000 Italian Liras (about  
300 US Dollars). A limited number of prizes covering the registration  
fee and the expenses for Hotel accommodation will be awarded for  
selected abstracts.**

**Application forms and abstracts should be submitted before March  
10, 1989 to:**

Servizio Attività Culturali Istituto Nazionale per la Ricerca sul Cancro  
Viale Benedetto XV, 1016132 GENOVA, Italy (W5893)C

**Call for Papers**

**EIGHTH INTERNATIONAL OCEAN DISPOSAL  
SYMPOSIUM (8IODS)**

**Dubrovnik, Yugoslavia — 9-13 October 1989**

The overall objectives and scope of 8IODS are:

- Provide a forum for exchange of ideas and information among investigators involved in marine pollution and oceanic disposal research
- Enhance the scientific consideration of waste disposal and marine pollution processes.
- Generate recommendations and guidelines for future studies of oceanic disposal practices.

The 8IODS will feature special sessions and invited keynote speakers. The Co-Chairman of 8IODS are: Dr. Velimar Pravdic, Ruder Boskovic, Zagreb, and Dr. Adam Benovic, Biological Institute, Dubrovnik, Yugoslavia.

Send 250-word abstract by 31 May 1989 to:

**Dr. Iver W. Duedall, Organizing Committee Co-Chairman,  
Department of Oceanography and Ocean Engineering,  
Florida Institute of Technology, Melbourne, Florida 32901  
USA. (NW3381)M**

**Molecular Communication in Higher Plants**

**18-21 September 1989**

**at EMBL, Heidelberg, F. R. Germany**

**Invited speakers include:**

D. Baulcombe (GB-Norwich), M. Bennett (GB-Kew), M. Bevan (GB-Cambridge), T. Bisseling (NL-Wageningen), U. Bonas (D-Berlin), C. Bowler (B-Gent), F. de Bruijn (D-Köln), M. Caboche (F-Versailles), N.-H. Chua (USA-New York), A. Clarke (Australia-Melbourne), E. Coen (GB-Norwich), G. Coruzzi (USA-New York), J. Dangi (D-Köln), E. Dennis (Australia-Canberra), A. Gatenby (USA-Wilmington), W. Gerlach (Australia-Canberra), A. Gierl (D-Köln), R. Goldberg (USA-Los Angeles), W. Gruissem (USA-Berkeley), R. Hedrich (D-Göttingen), T. Hohn (CH-Basel), R. Horsch (USA-St. Louis), D. Jofuku (B-Gent), J. Jones (GB-Norwich), J. Leemans (B-Gent), P. Meyer (D-Köln), D. Mohnen (USA-Athens), T. Nelson (USA-New Haven), K. Palme (D-Köln), I. Potrykus (CH-Zürich), P. Quail (USA-Albany), E. Schäfer (D-Freiburg), A. Sievers (D-Bonn), C. Somerville (USA-East Lansing), A. Spena (D-Köln), D. van der Straeten (B-Gent), A. Trewavas (GB-Edinburgh), S. C. de Vries (NL-Wageningen), E. Weiler (D-Bochum), P. Weisbeek (NL-Utrecht), U. Wienand (D-Köln), L. Willmitzer (D-Berlin).

**There will be nine plenary sessions which will cover:**

Cell-cell interactions; Differential gene expression/mutational analysis of plant function; Inter and intracellular signalling and the regulation of plant growth; Plant and environment; Plant biotechnology; Plant and microbes; Plants and viruses; Protein traffic and assembly into higher order structures; Structure, modification and expression of the nuclear genome (including novel techniques for gene isolation). The two poster sessions will allow participants to present their work.

**Registration:**

The Symposium will be at the European Molecular Biology Laboratory, Heidelberg, with registration on Sunday, 17 September 1989. The registration fee, which includes daily transport to and from the EMBL, lunches, and the Symposium reception, is DM 180, for graduate students DM 90, and for participants from industry DM 360. Participants will be accommodated in the EMBL guest house and hotels in Heidelberg. The registration fee does NOT cover the cost of accommodation.

**Application:**

The deadline for applicants is 16 June 1989. Applications should include a curriculum vitae and a brief description of research interests. The organizing committee will notify those who have been accepted as soon as possible after the deadline. The total number of participants will be limited to 250. Applications should be addressed to **Dr. J. Tooze, EMBO, Postfach 102240, D-6900 Heidelberg, F. R. Germany**. Applicants wishing to present a poster should send a 1-page abstract together with the registration fee and reply sheet after they have been accepted for participation.

**Organizing committee:**

C. Leaver (Edinburgh) –Chairman–, K. Marcker (Aarhus), M. van Montagu (Ghent), I. Potrykus (Zürich), H. Saedler (Köln), F. Salamini (Köln), J. Tooze (EMBO, Heidelberg). (W5907)M

**COLD SPRING HARBOR LABORATORY  
CONFERENCE ON  
YEAST CELL BIOLOGY**

**AUGUST 15 - 20, 1989**

**Organized by:**

Scott Emr, *California Institute of Technology*  
Amar Klar, *NCI, Frederick Cancer Research Facility*  
John Pringle, *University of Michigan*  
Steve Reed, *Scripps Clinic & Research Foundation*

**Topics to be covered will include:**

- Cell cycle controls
- Developmental choices
- Cell-cell recognition
- Cytoskeleton and cell structure
- Organelle structure and function
- Protein targeting and modification
- Elements of chromosome structure and function

**The abstract deadline is May 31, 1989.**

**Registration & abstract materials may be obtained from:**

**Meetings Coordinator**

**Cold Spring Harbor Laboratory**

**Cold Spring Harbor, NY 11724**

**516-367-8346 FAX 516-367-8845**

**1989**

# PHILIPPE LAUDAT CONFERENCES

**LE BISCHENBERG • OBERNAI**

## ★ Human mitochondrial diseases : clinical features, biochemistry and molecular genetics of oxidative phosphorylation defects

**★ OCTOBER 1-5 1989**

### Preliminary Programme :

Mitochondrial DNA : function, maternal heredity, deletions, mutations

Defects in complexes I, III and IV of the respiratory chain

New investigative methods for mitochondrial cytopathies

Strategy for therapy

Animal models for mitochondrial myopathies.

## ★ The neuroendocrine-immune network : molecular aspects ★ OCTOBER 15-19, 1989

### Preliminary Programme :

Heterologous actions of hormones and cytokines

Neuromediators and immune function

Neuroendocrine peptides and immunity

Hormones and immunity

Cellular origin and functions of « ectopic » signals

Signals transduction

Antigenic mimicry

Integrated topics : clinical correlates.

## ★ Bacterial pathogenesis, from molecular genetics to cell biology

**★ OCTOBER 22-26, 1989**

### Preliminary Programme :

Bacterial genetics : new tools to study pathogenesis

Bacterial attachment, phagocytosis, cellular traffic

Bacterial invasion, movement of cell organelles

Bacterial toxins, G-proteins, cytoskeleton.

Posters sessions are also planned for each conference.

Scientists wishing to attend these conferences can obtain informations and application forms at the following address :  
INSERM SYMPOSIA DEPARTMENT, 101, rue de Tolbiac, 75654 PARIS CEDEX 13, France — Telephone : 45.84.14.41  
ext. 4065 and 40101 — Telex : INSERM 270 532 F — fax : 45.85.68.56

## UNIVERSITY OF LEICESTER M.Sc. IN MOLECULAR GENETICS (commencing 18 September 1989)

**Course outline:** Intensive practical training given in molecular genetic techniques and recombinant DNA technology, formal instruction in microbial genetics, study of gene expression and the physiology of molecular biology of a range of host cell systems, all supported by a seminar and tutorial programme; development of a research project undertaken in the Life Sciences.

**Assessment:** course is examined by means of continuous assessment and presentation of a Project Report on completion in June 1990.

**General:** The course is designed as a link for graduates in Biological Sciences and related subjects who wish to prepare themselves for employment in molecular biology and biotechnology or for entry to a higher degree by research. According to qualifications overseas students may be required to undertake a one year Foundation Studies programme in preparation for entry to the course. A limited number of bursaries are available for suitably qualified applicants. The course has been recognised for support by the SERC and MRC.

**Application forms and further details:** Please address all enquiries and requests for further details to the Higher Degrees Office, University of Leicester, Leicester LE1 7RH, U.K. (telephone (0533) 522298). (8568)C

## 1989/90 INTER-UNIVERSITY MSc COURSE ON THE PHYSICS AND TECHNOLOGY OF AMORPHOUS MATERIALS

Universities of Dundee—Edinburgh—Glasgow

The one year advanced course, in this rapidly developing field, is offered jointly by the above named Universities. Course work will be given at the University of Dundee. For the project work, students will join a research group at one of the participating institutions.

Applications are invited from students with an honours degree (or its equivalent) in either Physics, Electrical Engineering, or a Materials Science. The course has been approved by the Science Research Council and Advanced Course Studentships are available for suitably qualified applicants.

Further information may be obtained from: **Professor W. E. Spear, FRSc, Carnegie Laboratory of Physics, The University, Dundee DD1 4HN.** (8542)C

## ANNOUNCEMENTS

## CALL FOR PAPERS

The editors of

**Diagnostics**  
& CLINICAL TESTING

a new journal from the publishers of Nature and Bio/Technology  
for technical managers in clinical laboratories,  
seek first-class research articles and technical notes on new  
diagnostic and clinical-testing technologies.

We are particularly eager to publish the first reports of  
techniques and protocols that promise widespread practical  
application.

Please submit papers of up to 3,500 words to

**Patricia Dimond, Ph.D.**  
**Senior Editor**  
**Diagnostics & Clinical Testing**  
**Nature Publishing Co.**  
**65 Bleeker St.**

## 5 good reasons why you should advertise your jobs and conferences in Nature

*your advertisement will  
reach over ½ million  
scientists worldwide*

*our quality readership  
promises a quality  
response*

*we guarantee to publish  
your advertisement  
faster than any  
other international  
science weekly*

*our competitive rates  
represent the lowest  
cost per 1000 readers*

*you will receive prompt  
service and helpful  
advice*

**Contact us  
and we'll tell you more**

# Introducing Stratagene's New 1989 Catalog

*Contains detailed information  
on the latest products and services  
for all your molecular  
biology needs.*

## Stratagene's 1989 Catalog Features:

- ▶ **Stratalinker™**: Crosslink DNA and RNA to nitrocellulose or nylon membranes in just 30 seconds.
- ▶ **ThermalBase™ Kit**: DNA sequencing using Taq Polymerase I. Successful sequencing through G-C rich regions.
- ▶ **Custom Libraries**: > 10<sup>6</sup> primary plaques in 2-3 weeks. Also available: large assortment of premade cDNA and genomic libraries prepared by Stratagene.
- ▶ **Zap™ cDNA Synthesis Kit**: High efficiency Uni-directional Cloning.
- ▶ **VAGE™ System**: Southern and Northern gels and blotting in 3 hours instead of 30.
- ▶ **Lambda Zap™ II**: Lambda phage to pBluescript II without subcloning. Enhanced color selection.
- ▶ **Gigapack™ Gold**: Highest commercially available packaging extract. Greater than 2 x 10<sup>9</sup> plaques/ug.
- ▶ **Epicurean™ Coli**: High efficiency competent E. coli. (> 10<sup>9</sup>/ug)
- ▶ **Restriction & Modifying Enzymes**: Very large selection.
- ▶ **Next Day Delivery**: Available on U.S. orders until 6PM EST.
- ▶ **Technical Support**: Provided by experienced scientists.

**To receive a FREE copy of the new catalog or more  
information on any of our kits or services, call:

INTERNATIONAL WEEKLY JOURNAL OF SCIENCE

Volume 338 No. 6213 23 March 1989 £1.95

**HETEROCHRONIC GENE  
EXPRESSION IN DEVELOPMENT**

CUK-H06895-319-P 36657

# We specialize in quality, custom peptide synthesis . . . so you don't have to!

Our proprietary techniques enable MPS to supply you with all the custom peptides you need. For example, we can provide over 100 completely different 15-residue peptides in as little as three weeks. An analytical HPLC chromatogram is included with each peptide ordered.

MPS offers quality peptides with service we're sure you'll like. Call us with your questions or if you would like a complete price list.

MPS also provides a custom HF Cleavage Service and a unique HF Cleavage System.

## COMPARE OUR PRICES

MPS is offering custom peptides at the extraordinary prices listed below.

10mer	\$400
15mer	\$550
20mer	\$800

Prices are based on 50mg of HF Cleaved Peptide. 4 to 6 weeks delivery, minimum order of 3 peptides or \$1000.

## CAN YOU SYNTHESIZE PEPTIDES FOR LESS?

Before you buy an automated peptide synthesizer, you should consider the actual cost for in-house synthesis which includes the cost of reagents, personnel, service contracts, analysis, waste disposal, downtime and, of course, the initial cost of the synthesizer.

HPLCs of unpurified, HF cleaved peptides

# Change Your Mind...

ABOUT PLASMID PREPS

**FORGET...** 1 liter cultures

**THINK SMALL...** small volume cultures in CIRCLEGROW high density growth medium.

**FORGET...** enzyme digestions and organic extractions

**THINK SIMPLE...** isolate plasmid DNA without lysozyme, protease or RNase digestions; phenol or chloroform extractions.

**FORGET...** extended CsCl/EtBr isopycnic spins and

**THINK FAST...** less than 90 minutes from cell pellet to purified plasmid DNA.

Think about it... Why expend the time and effort to isolate a milligram of plasmid DNA when you really need less than 5% of that amount for most cloning projects... Especially now that the CIRCLEPREP KIT allows you to get enough DNA to do what needs to be done quickly... 90 minutes from cell pellet to purified plasmid DNA... 50 to 100 ug of substrate-quality plasmid DNA that will cut and ligate every time... Think about it... but don't think too long.

# CIRCLEPREP™

RAPID PLASMID DNA PURIFICATION KIT

Isolate preparative quantities of enzyme substrate-quality plasmid DNA in 90 minutes.

patent pending

60 MINUTES

CLEARED LYSATE

## CIRCLEPREP Kit, cat. #CP100

Kit contains all reagents necessary to grow cells, prepare cleared lysate and purify preparative quantities of enzyme substrate-quality plasmid DNA.

20 plasmid preps per Kit each typically yielding 50 ug of enzyme substrate-quality plasmid DNA per prep.

To order **CIRCLEPREP** Kit or for further information:

Reader Service No.637

# There's still the odd place we don't fly to.

It's a remote possibility, but if your business should take you to the South Pole, sadly, Swissair can't.

A conference in Karachi, however, a meeting in Moscow or a seminar in Sao Paulo? No problem.

Swissair fly to over a hundred destinations, across five continents

(including, of course, all the best connections out of Switzerland).

And we do it in a style that has attracted more awards than any other airline.

Swissair isn't just about where you fly, but how you feel when you get there.

**swissair** 

**How very civilised.**

Reader Service No.2

# Protein G

## Engineered to perfection

Protein G Sepharose® 4 Fast Flow is the new affinity chromatography medium for the specific separation and purification of polyclonal IgG and monoclonal IgG of different subclasses. With its wider binding specificity, it complements Protein A Sepharose CL-4B – a gel already documented in thousands of references.

Protein G Sepharose 4 Fast Flow has been engineered to perfection by matching the optimized ligand with the best available matrix. Our Protein G is an engineered, recombinant product from which the albumin-binding region has been deleted genetically. The base matrix, Sepharose 4 Fast Flow, was selected after extensive evaluation in search of optimal capacity and flow rate.

The new gel complements Protein A Sepharose CL-4B by binding

- a wide range of IgG's, including human, mouse, rat, cow, goat, sheep, horse, and many others
- specific subclasses including human IgG<sub>3</sub>, mouse IgG<sub>1</sub>, IgG<sub>2a</sub> and IgG<sub>2b</sub>, and rat IgG<sub>2a</sub> and IgG<sub>2b</sub>.

Protein G Sepharose 4 Fast Flow is excellent for separating monoclonal antibodies from ascites and from cell culture fluid. The gel binds more than 20 mg human polyclonal IgG/ml drained gel; a capacity unrivalled by any other commercial preparation.

In addition, Pharmacia LKB also supplies unbound recombinant Protein G for testing and analysis.

Order your Protein G products today or ask your representative for the Data Sheet.

Product	Code No.	Pack size
Protein G Sepharose 4 Fast Flow	17-0618-01	5 ml
Protein G Sepharose 4 Fast Flow	17-0618-02	25 ml
Protein G	17-0619-01	5 mg

# nature

23 March 1989

Vol. 338 Issue no. 6213

The cover illustrates the use of immunofluorescence staining to locate the product of the heterochronic gene *lin14* in an embryo of the nematode *Caenorhabditis elegans*. The gene encodes a 'temporal development switch', as described in the Article on page 313.

## THIS WEEK

### Scrapie-like syndrome

Gerstmann-Sträussler syndrome, a rare neurodegenerative disease with infectious properties that can also be inherited, is associated with a very rare amino acid substitution in the 'prion' protein, page 342. And see 'Sheep disease in human clothing', page 298.

### Synthesis and use

Workers from AT&T Bell Laboratories describe a method of synthesizing the '124' superconductor without the need for specialized equipment, page 328. On page 330, an application for high- $T_c$  superconducting ceramics in the separation of paramagnetic and diamagnetic molecules.

### Brain waves

Oscillatory responses of widely separated neurons in the visual cortex of the cat are shown to be synchronized if the cells have the same orientation properties. This may be a mechanism for establishing relationships between stimuli in different parts of the visual field, pages 334 and 297.

### Voyager's best shot

The highest-resolution image from Voyager II of Uranus's moon Umbriel (below) shows a dark, heavily cratered surface. Photometry data suggest that present

surface patterns are the result of tectonic disruption early in the lifetime of the moon, page 324.

### Pulsar in theory

The odd properties of the recently discovered pulsar in supernova 1987A have provoked competition among theoretical astrophysicists. Is the neutron star not rotating but vibrating (page 319)? If it is rotating, was it born spinning 2,000 times a second, or has it been spun up by accretion (page 321)? For a sober assessment of problems and possibilities, see page 295.

### Cyclins A and B

Cyclins are proteins that vary in concentration with the cell cycle, rising until mitosis then falling sharply. Of two cyclins in the fruit-fly *Drosophila*, maternal mRNA for one becomes localized in the pole cells destined to form the germ line of the developing fly. This cyclin B may have a specialized function in regulating germ-cell proliferation, page 337.

### Chromosome probes

Chromosome 8 (arrowed), target

for a microdissection technique for isolating probes for defined regions of the human chromosome. Page 348.

### Atmospheric pollution

Measurements taken at the mountain-top Mauna Loa Observatory in Hawaii point to fossil fuel burning in the United States as a source of soluble atmospheric nitrogen over the island in summer and autumn. Page 326.

### Author Index

Facing page 360 this week is the Author Index for Volume 337, including a Guide to Authors.

## TAKE A CLOSER LOOK AT PEPTIDE PURITY

*New Bio-Rad HPE™ 100 : High Performance Electrophoresis : sensitivity and speed*

The HPE™ 100 System offers an exciting new way to look at peptide and protein purity:

### **APPLICATIONS :**

- ◊ Peptide purity
- ◊ Tryptic mapping
- ◊ Detection of deamination
- ◊ Protein analysis
- ◊ DNA fragment separation.

### **ADVANTAGES:**

- ◊ Easy-to-handle cartridge capillaries
- ◊ Patented coating in the capillary prevents electroendosmosis
- ◊ Picogram sensitivity in the capillary
- ◊ Free zone or isoelectric focusing modes
- ◊ Low cost per analysis
- ◊ HPE™ 100 is supported by a full service organisation

Call your local Bio-Rad representative to discuss what HPE™ 100 can do for you now and in the future.

# Did you know?

The greatest force generated in nature is the 400g averaged by the click beetle (*Athous haemorrhoidalis*) when jack knifing into the air to escape predators. This resilient beetle endures a peak brain deceleration of 2300g during the movement.

"...a major breakthrough in the field of molecular biology..." —SIM News

"It is having a revolutionary impact." —H.H. Kazazian, Johns Hopkins University

## PCR TECHNOLOGY Principles and Applications for DNA Amplification

Edited by Henry Erlich, PhD, Senior Scientist and Director of Human Genetics, Cetus Corporation  
PCR (Polymerase Chain Reaction) technology is a revolutionary technique which enables scientists to rapidly generate large amounts of genetic material from a slight trace which would otherwise be too small to analyze. With applications in both research and diagnostics, PCR will soon become a standard procedure in biotechnology and medical diagnostic laboratories. *PCR Technology: Principles and Applications for DNA Amplification* is an introduction and guide to the technology. Written by the pioneers in the field, this is the authoritative publication detailing the methodology and the wide range of applications of PCR technology, including medicine, evolution and forensics.

### Projected contents: INTRODUCTION TO THE PCR

History of PCR Development—Brief Essay • Description of the PCR Method—Basic Principles and Properties of the PCR • Thermostable DNA Polymerases • Automation • Sample Preparation  
RESEARCH APPLICATIONS—BRIEF OVERVIEW

Direct Sequencing Using PCR • Preparation of Specific DNA Fragments Using PCR • Detection of Gene Expression • Genetic Mapping Using PCR Amplification of Individual Gametes  
DIAGNOSTIC APPLICATIONS—BRIEF OVERVIEW

Detection of Pathogens • Diagnosis of Monogenic Genetic Diseases • HLA DNA Typing and Disease Susceptibility • Forensic Applications • Detection of Activated Oncogenes • Future Developments and Applications—Brief Essay

# ...and did you know?

that Pharmacia LKB sell a range of spectrophotometers. An interesting fact that not enough people currently know, but it won't last. As the athletic exploits of the click beetle become common knowledge, so will the performance of our simple to use range of UV/vis spectrophotometers. To discover more, simply telephone your local Pharmacia LKB office or use the reader enquiry system for a complete information pack (including a free wallchart) and stay one *jump* ahead!

**BIOTECHNOLOGY AND THE ENVIRONMENT:**  
**International Regulation**

**Jeffrey Gibbs, Iver Cooper, Bruce Mackler**

**Announcing the first comprehensive analysis of environmental regulation in biotechnology.**

- **Reviews all aspects of U.S. regulatory policy**  
United States Environmental Protection Agency and biotech-related statutes – National Institute of Health Guidelines – United States Department of Agriculture's role – Food and Drug Administration – Coordination of federal regulation – National Environmental Policy Act – Endangered Species Act – Laws relating to transportation of products – Product liability suits brought by private citizens – Regulation by local governments
- **Describes the regulatory status of eleven industrialized countries in eleven different chapters**  
The United Kingdom – Australia – Austria – Canada – Denmark – the Federal Republic of Germany – France – Ireland – the Netherlands – New Zealand – Switzerland. Chapters were prepared by a contributing author from the subject country.
- **Analyzes international regulatory patterns and predicts future trends.**  
Environmental regulations in biotechnology have evolved dramatically. The authors examine the past patterns of this evolution, review current policies, and speculate as to what regulations may be in the future.
- **An invaluable source source for professionals in biotechnology, the law, and regulatory affairs**  
*Biotechnology and the Environment* is presented clearly and succinctly to benefit biotechnology and regulatory affairs professionals as well as lawyers and government regulators. The book places biotechnology in the context of general environmental regulation and describes how the present regulatory framework will accommodate biotechnology.
- **Three authors bring you their expertise as authorities on biotechnology regulation**  
Jeffrey Gibbs is Associate General Counsel for the Association of Biotechnology Companies and has written and lectured extensively on regulatory issues. Iver Cooper is the author of *Biotechnology and the Law*, and many articles on patent law. Dr. Bruce Mackler is general counsel to the Association of Biotechnology Companies. He specializes in microbiology and immunology, and is managing editor of the *Biotechnology Law Report*. All three authors are partners in the Washington, D.C. law firm of Mackler, Cooper and Gibbs. Order now on free approval by mail or phone. We accept all major credit cards.

# GET THE KNOWLEDGE YOU NEED

## March 28-30, 1989 • Hyatt Regency

- The significant research
- The newest methods
- The latest products
- The notable experts
- The industry contacts
- The financial synergy
- The international perspective

AgBIOTECH '89 features a multi-track professional seminar program that only the editors of BIO/TECHNOLOGY could produce. And it's *all-ag*, all aspects — from lab to production to marketing to regulation.

### Science/Technical

You'll hear leading researchers responsible for the most significant and splendid advances in transgenic crops and genetic engineering techniques discuss their research.

### Business/Regulatory

You'll hear experienced industry executives with in-the-trenches experience discuss what has worked, what is economically viable, regulation, patenting, and future development.

If you're in ag-biotech — and determined to stay competitive in the '90's — you can't afford to miss this stimulating program! REGISTER TODAY!

### A Faculty Of More Than 75 Ag-Biotech Experts Including:

Gordon Ada, Johns Hopkins University  
 \*Charles Arntzen, Texas A&M University  
 \*Harvey Bialy, Bio/Technology  
 Charles Baker, BioTechnica Agriculture  
 Andrew Barnes, Mycogen  
 Kenneth A. Barton, Agracetus  
 Jacques S. Beckmann, The Volcani Center  
 David Beier, Office of Congressman Robert Kastenmeier  
 Joseph Bouckaert, Advanced Genetic Sciences  
 \*Fred Brown, Wellcome Biotech  
 \*G. Steven Burrill, Arthur Young  
 \*Edgar R. Butts, E.R. Butts International  
 John Cantrell, RIBI Immunochem  
 \*Jerry Caulder, Mycogen  
 Joel I. Cohen, Agency for International Development  
 Luca Comai, Calgene  
 Abhaya Dandekar, University of California  
 Hugo Donner, Advanced Genetic Sciences  
 Adele Douglas, Humane Society  
 Jack Doyle, Environmental Policy Institute  
 Raymond Dull, Experience, Inc.  
 Christopher Earl, Plant Resources Venture Fund  
 \*Gary B. Ellis, U.S. Congress Office of Technology Assessment  
 JoAnn Fillatti, Calgene  
 Ray Fuchs, Monsanto Agricultural  
 Val Giddings, The World Bank  
 David J. Glass, BioTechnica Agriculture  
 Kathi Hanna, U.S. Congress Office of Technology Assessment  
 Tim Helentjaris, Native Plants  
 Maude Hinchee, Monsanto Agricultural  
 Curt Hutchinson, Wildlife International  
 Daniel D. Kahn, Institute National De La Recherche Agronomique  
 Robert D. Kahn, Robert D. Kahn & Co.  
 George H. Kidd, L. William Teweles & Co.  
 \*Kelly Kincannon, Kincannon & Reed  
 Christopher Lamb, Salk Institute  
 Richard Laster, DNA Plant Technology  
 Howard Lyman, National Farmers Union  
 Joel S. Marcus, Pettit & Martin  
 William Marshall, Pioneer Hi-Bred International

## PROGRAM

### BUSINESS FORUM

8:00 a.m. – 11:00 a.m.

Management Strategies  
 Market Sizes and Structures  
 Long Range Strategic Planning

Chair: David Wheat  
 Panelists: A. Barnes, G. Kidd, R. Laster

11:00 a.m. – 2:00 p.m.:

2:00 p.m. – 5:00 p.m.

Management Strategies  
 International Strategic Alliances  
 High Level Staffing

Chair: Kelly Kincannon  
 Panelists: C. Baker, J. Bouckaert, J. Marcus

Tuesday, March 28

8:00 a.m. – 11:00 a.m.

Regulation: Case Studies; Testing for Registering Microbial Pesticides

Chair: Edgar R. Butts and Robert B. Nicholas  
 Panelists: D. Glass, C. Hutchinson, R. Kahn, J. Panetta, F. Serdy, J. Swigert, S. Woodhead

11:00 a.m. – 2:00 p.m.:

2:00 p.m. – 5:00 p.m.

Commercial Financing

Chair: G. Steven Burrill  
 Panelists: C. Earl, R. Moshe, L. Stern, D. Wagster

Wednesday, March 29

8:00 a.m. – 11:00 a.m.

Patents: Animal; Plant

Chair: Kathleen Merrigan  
 Panelists: D. Beier, A. Douglas, J. Doyle, H. Lyman, L. McKenzie, K. O'Conner, R. Quisenberry

11:00 a.m. – 2:00 p.m.:

1:30 p.m. – 4:30 p.m.

Government Research Funding Policies

Chair: Gary B. Ellis  
 Panelists: R. Dull, V. Giddings, K. Hanna, W. Marshall, M. Phillips, J. Tavares

Thursday, March 30

# CANCER TITLES

*from Macmillan*

## Tumor Diagnosis by Electron Microscopy Volume 2

*Edited by Jose Russo, Michigan Cancer Foundation, Detroit and Sheldon C Sommers*

This new book brings together contributions from the worlds of academic and practical pathology. The contributors have a wide experience of various areas of systematic organotypic pathology and electron microscopy.

**Contents:** The use of Electron-Immunocytochemistry in Tumor Diagnosis; R.A. Detellis / New Technical Perspectives of Electron Microscopy in Diagnostic Medicine; J. Johnson, Jr. / Electron Microscopy of the Main Neoplastic Lesions of the Skin; B. MacKay / Ultrastructural Distribution of Tumor Associated Antigens and Cell Markers in Breast Carcinoma; J. Russo, L. Tait, A. Jimenez-Tabata & I.H. Russo / Ultrastructural Appearance of Tumors of the Lung; R. Sibley / Ultrastructure of Neuroendocrine Tumors; E. Horvath / The Langerhans Cells in the Immunocompetence of the Human Cervix, Ultrastructure and Immunocytochemistry; C.F. de Vargas & I.H. Russo / Electron Microscopy in the Diagnosis of Testicular Tumors; R. Sibley / Electron Microscopy of Tumors of the Central and Peripheral Nervous System Including Meninges; R.A. Erlandson  
1988 250pp Hardback £56.00 02-404910-7 Published by Collier Macmillan

## An Atlas of Brachytherapy: Principles, Techniques, and Clinical Applications

*Basil S Hilaris, Datattreydu Nori, and Lowell Anderson, all of Cornell University, College of Medicine and Memorial Sloan-Kettering Cancer Centre*

This well illustrated book covers all aspects of brachytherapy. It provides a quick and easy reference to practical management of malignant diseases.

**Contents:** Introduction / Radionuclides for Brachytherapy / Brachytherapy Instruments / Brachytherapy Techniques / Brachytherapy Treatment Planning and Evaluation / Radiation Protection / Clinical Applications of Brachytherapy / Head and Neck / Brain / Breast / Soft Tissues Sarcoma / Lung / Pancreas / Prostate / Bladder / Cervix / Corpus / Vagina / Vulva / Female Urethra / Terminology / Index  
1988 Hardback £56.00 02-354770-7 Published by Collier Macmillan

## Cost Versus Benefit in Cancer Care

*Edited by Basil Stoll, Honorary Consultant, St Thomas' Hospital, London*

In view of spiralling health costs in Western countries, physicians on both sides of the Atlantic must reach agreement on what is 'appropriate' treatment for patients with advanced cancer. This book is the first to expose the dilemma between cost and benefit in the treatment of advanced cancer. It is written for physicians, who ultimately have to make the choices in allocating resources, and discusses frankly the reasons for differences in treatment across the Atlantic.

**Contents:** Introduction; G. Mooney PART 1 CURRENT DILEMMAS What is Overtreatment in Cancer? B.A. Stoll What is Best for the Patient? United States View; A.U. Buzdan What is Best for the Patient? European View; G.J.G. Rees The Patient's Expectations in the United States; A.S. Brett The Physician's Attitude in Britain; D. Radstone Focus on Clinical Trials; E.A. Eisenhauer & W.J. Mackillop PART 2 FUTURE PROSPECTS Dying with Dignity; United States View; B. Lo & F. Rouse Dying with Dignity; British View; S. Ahmedzai & E. Wilkes Rationing Cancer Care; United States View; E. Ginzberg Rationing Cancer Care; European View; G. Mooney & J. Henderson Saying No is Difficult in Cancer; B.A. Stoll Index  
1988 144pp 234x156mm Hardback £25.00 0-333-43594-X

## Clinical Cancer Monographs

Clinical Cancer Monographs is a new series presenting the data compiled by the English West Midlands Regional Cancer Registry, by site of malignancy. The unique feature of the series is the presentation and analysis of data not just on incidence, but also on treatments and the effect of treatments on survival. The records used in the analysis cover a 25 year period and a population of 5 million people, with demographic characteristics which serve as a useful model for other regions in industrialized countries. The series will be of great value to oncologists and clinicians as well as health planners and medical statisticians.

ISSN 0954 7495

### Volume 1 Cancer of the Oesophagus

*H R Matthews, Consultant Surgeon and Clinical Oncologist, Queen Elizabeth Medical Centre, Birmingham, UK; J A H Waterhouse, Director, West Midlands Regional Cancer Registry, (WMRCR) Birmingham, UK; J Powell, Epidemiologist, WMRCR; C C McConkey, Statistician, WMRCR; and J E Robertson, WMRCR.*

**Contents:** Introduction and Methods / Epidemiology / Demographic Aspects / Histology / Overall Survival / Treatment / Survival after Treatment / Atypical Tumours / Appendices  
1987 184pp 234x156mm Hardback £48.00 0-333-42768-8

### Volume 2 Cancer of the Larynx

*P E Robin, Consultant ENT Surgeon, West Birmingham Health Authority; J Powell, Epidemiologist, West Midlands Regional Cancer Registry (WMRCR), Birmingham, UK; G M Holme, Queen Elizabeth Hospital, Birmingham; J A H Waterhouse, Director, WMRCR; C C McConkey, Statistician, WMRCR; and J E Robertson, WMRCR.*

**Contents:** Introduction and Methods / Epidemiology / Demographic Aspects / Multiple Primaries, Social Class and Occupation / Histology / Incidence by Sub-Site / Stage / Overall Survival / Treatment / Survival Related to Treatment / Second Treatments / Appendices  
1988 236pp 234x156mm Hardback £40.00 0-333-47265-9

### Volume 3 Cancer of the Stomach

*J W L Fielding, Consultant, Queen Elizabeth Medical Centre, Birmingham, UK; J Powell, Epidemiologist, West Midlands Regional Cancer Registry (WMRCR), Birmingham, UK; W H Allum, Consultant, Queen Elizabeth Medical Centre, Birmingham, UK; J A H Waterhouse, Director, WMRCR; and C C McConkey, Statistician, WMRCR*

# Get up to 300% more activity from your immobilized antibodies

New Affi-Gel® Hz immunoaffinity support from Bio-Rad for Fc fragment-specific antibody immobilization.

Fig. 1. Binding of <sup>14</sup>C-BSA to anti-BSA IgG immobilized on Affi-Gel Hz and CNBr Sepharose® supports.

Fig. 2. Binding of <sup>14</sup>C-beta-galactosidase to anti-beta galactosidase IgG immobilized on Affi-Gel Hz and CNBr Sepharose supports.

The comparison shown here between the Bio-Rad method\* and another manufacturer's method clearly demonstrates a dramatic increase in activity with two different antibodies.

## Affi-Gel Hz support advantages:

- Antibody activity is preserved by immobilization through the carbohydrate moiety of the Fc fragment.
- Chemically stable, covalent coupling chemistry
- Increased immobilized antibody activity
- Convenient kit format and bulk quantities available

For further information, contact your local Bio-Rad representative today.

\*Patent pending

## DIRECT PROTEIN TRANSFER INTO CELLS & OOCYTES

**Q:** *What is this?*

**A:** This is a new technique to **directly, simultaneously, reproducibly, and rapidly** transfer protein molecules into **many** cells and oocytes by **BAEKON Transfer System**.

**Q:** *What kinds of protein have you tried to transfer with this technique and what are their molecular weights?*

**A:** So far, we have tried many proteins including antibodies, structural proteins, regulatory factors, and enzymes. Their MW ranges from 20–160 kD.

**Q:** *Are the proteins active/functional inside the recipient cells?*

**A:** Yes, they are fully functional. For structural proteins, they can be assimilated as cellular components; for enzymes, they retain enzymatic activities; for antibodies, they inhibit respective cellular processes.

**Q:** *What are the recipient cells?*

**A:** Culture cell lines, e.g., 3T3, PC-12; primary culture; human, mouse, *Xenopus*, and *Drosophila* oocytes.

**Q:** *What percentage of the cells get transferred?*

**A:** Greater than 95%.

**Q:** *Are the recipient cells viable?*

**A:** Yes, viability is greater than 95%.

**Q:** *Can post-transferred oocytes and embryos develop normally?*

**A:** Yes.

**Q:** *What can I do with this technique?*

**A:** A lot: to study the function and localization of a gene product, and to regulate gene expression by transferring specific gene products, regulatory factors, enzymes, or antibodies into cells. **Imagine ...!**

**Q:** *What instrument have you been using for the transfer experiments?*

**A:** **BAEKON 2000\*** If you want to know more about this instrument and the whole scope of application, protocols, as well as experimental details, please contact **BAEKON**.

**BAEKON, INC.**  
18866 Allendale Ave.,  
Saratoga, CA 95070  
U.S.A.

**Phone: (408) 741-0404**

**FAX: (408) 741-0944      Telex: 362943 baekon ud**

\*This instrument has successfully been used to transfer genes into mammalian cells (T- & B-lymphocytes, hepatocytes, fibroblasts, kidney & neural cells, etc.), plant cells (monocot & dicot, both intact cells and protoplasts) and bacterial cells (Gram positive & negative). It also has been used to induce cell fusion among mammalian, fish, plant, and bacterial cells.

## More wicked ways with hormones

The European Commission has hung an intellectual millstone around its neck by banning the use of bovine growth hormone in growing cattle. The European Parliament has a duty to put it straight.

VISIONARIES who proclaim that the United States of Europe is no further away than 1992, when the European Economic Community will constitute the single market originally decreed by the Treaty of Rome, habitually overlook the still-glaring differences between Europe and the United States. True, Europe has a president (now M. Jacques Delors), but does not require that he should be elected as Mr George Bush has been. And while the members of the European Commission (now 17 strong) are roughly analogous to members of a cabinet, they too are merely nominated every four years by the political heads of member governments. There is also a single-chamber European Parliament, the equivalent of the US Congress, which does suffer periodic re-election (next in June this year), but the opinion even among ardent Europeans is that the parliament will have to win influence in European affairs by demonstrating its value and good sense. The same Europeans will therefore be dismayed by one development last week — the decision of a parliamentary committee to support and even to reinforce the regulations that prohibit the use of bovine growth hormones in the fattening of cattle.

The circumstances are quite scandalous. Since the beginning of 1988, the sale in Europe of beef grown with the use of bovine growth hormone has been prohibited by a directive (with the force of law) of the European Commission. Although the measure has been justified as a means of protecting people's health, there is literally no evidence that beef produced with growth hormone is a hazard to health, but every reason to believe that bovine growth hormone in cattle is rapidly metabolized (which is why it helps cattle to grow more quickly). So why ban its use? Because Europe's system of support for agriculture is a means of over-producing all kinds of commodities, beef included, and because those administering the system were ready to clutch at any straw to prevent further surpluses of beef. What more natural than an alliance with the green extremists to keep the hormone out of use? Although imports of beef from the United States were exempted from restriction during 1988, this year began with an acrimonious trade dispute between Europe and the United States that rumbles on.

Now the European Parliament has entered the fray, but discredibly. Last week its environment committee in Luxembourg issued the gist of a report supporting the European Commission's ban and urging more vigilance in

tracking down now-illicit uses of these materials. The opportunity for extricating the Commission from the pit of unreason it had dug for itself has been spurned in the face of informed opinion and despite the diplomatic damage the ban has already caused. In the short run, the consequence will be more trouble. Unless the full parliament rejects the opinion of its committee in the discussion arranged for April, it will find that in the long run, it has much less influence than it might have won by acting sensibly, which should worry ardent Europeans, green and not-so-green. □

## Budgets off balance

Budget problems in Britain, the Soviet Union and United States may have different origins — but one solution.

AMONG the quaintest British customs is the annual ritual in which a person called the Chancellor of the Exchequer (now Mr Nigel Lawson) tells the House of Commons what taxes he plans to increase or decrease. The procedure is the inverse of what happens in most other places, where a government's annual budget is a statement of what it plans to spend coupled with a comparison of total spending and total revenue. In Britain, the spending estimates appear first, as fiat. That is why Lawson's performance last week (his sixth) has generally been written off as "dull" for, breaking with recent form, he offered neither tax breaks nor further imposts, except marginally.

But there is more than that to say. The British government is in the enviable position that its accounts are in surplus. In the year ending this month, there will be a surplus of £14,000 million. With the over-cautious forecast that next year's surplus will be the same, the British government could liquidate its entire debt within a decade. But is there nothing better to do with surplus funds than pay off debts? Not on British experience in the past few years. Putting more money in British pockets (either by reducing taxes or spending money) seems either to increase imports or industrial costs (through higher wages) — or both. Britain already has a trade deficit comparable with its budget surplus and slightly larger (as a percentage of Gross Domestic Product) than that of the United States. And inflation is pushing 8 per cent, so that interest rates have increased and sterling has

been allowed to increase in value against other European currencies. Lawson made a clean breast of his dilemma last week: despite the £14,000 surplus, he had no room for manoeuvre.

Notoriously, exactly the same is true in the United States, where the Deficit Reduction Act (better known as Gramm-Rudman after two of its three sponsors) puts a statutory and reducing ceiling (to be fixed finally only in the summer) on the federal budget deficit. Again, the government has no room for manoeuvre. Part of the trouble is that more than a third of US spending is fixed by various acts of Congress, while just under a third goes on defence. Because savings in the United States are not great enough to bridge the gap, the deficit has been financed by borrowing from elsewhere (which is why there is a trade deficit). Over the past 18 months, two devices have been used to correct the balance — interest rates have been increased (as in Britain) but the value of the US dollar has been allowed to decline. This house of cards depends on people's willingness to continue turning foreign currencies into dollars to bridge the gap; ideally, the lenders would have been given proof of a deal between the administration and the Congress early in the new presidency, but even optimists are now talking of cutting a deal only in the summer. The sharp if modest fall of the stock markets last week, ostensibly from fears of still higher interest rates, may be a sign that the delicate apparatus has begun to crumble.

Mr Mikhail Gorbachev is similarly hemmed in. The Soviet Union's budget is believed to be 20 per cent in deficit, but the consequent inflation is only marginally apparent because most prices are centrally controlled. Because there is so little on which people can spend money, they save it against the time when the shops are full again. Last week, Gorbachev outlined an agricultural reform that would have seemed revolutionary before he came to office; farmers are to be allowed personally to lease the land they farm on the grounds that they will then become more efficient, but the details are not yet made public and are probably still to be decided. One snag, not nearly as well advertised, is that even more efficient farmers will not grow more food unless prices are also increased, perhaps even by a free-market mechanism. Sadly, even the bare bones of the scheme will give ideological offence.

Why should three substantial governments be thus hamstrung? To compare the United States and the Soviet Union economically is absurd, but that is not the end of it. The United States is locked into a straitjacket because, despite the astonishing flexibility of its economy and the steady growth of production, expectations have stolen a march on real wealth. President Bush's hope, like his predecessor's, is that the United States will grow out of trouble, but even the present modest rate of growth is judged dangerously fast. The safer short-term remedy is modestly to reduce consumption, which the new president has promised he will not, but in the long run only an increase of productivity (rather than of mere production)

will square the circle. Exactly the same applies in the Soviet Union, but should be more achievable, given both the encouraging and the admonitory examples with which the world is littered. And, as it happens, the same long-term remedy is what Britain should also be looking for. The box in which Lawson is imprisoned would be less constraining if it were possible to spend (or give away) some or all of that budget surplus without rocking the boat. Maybe the three people chiefly concerned should put their heads together. □

## Universities in arms

British academics are faced with a nasty choice between a poor pay award and a continuing labour dispute.

THE reasons for believing that British academics are underpaid do not strain the imagination. Salaries have grown less quickly than those in other professional walks of life over the past decade of general deprivation for universities, and now compare so much less well than those in industry and elsewhere that university teachers and researchers are on the march to other jobs. The more serious worry is that recruitment to academic research at all levels is quickly drying up. Even school-leavers have learned that the academic profession is not much valued by the academic system's paymasters. Since the beginning of this year, academics have been declining to mark examination papers; now they have to choose between the continuation of that fruitless pursuit and their employers' offer of a salary increase of 6.5 per cent (which for practical purposes covers a two-year spell). The best course is to settle for what is on offer, but to prepare to fight a better battle next year.

The world, by now, knows that the vast majority of universities do not have the funds with which to pay more than they have offered. The whole world should also know that the British system cannot continue as in the past without running into serious difficulties. Hitherto, British academic pay has been determined nationally, by negotiation between the Association of University Teachers and the Committee of Vice-Chancellors and Principals. But the British university system is now well on the way to a welcome diversity in which some universities will be more able than others to pay good salaries. Disparities can only be further accentuated if the British government decides that the time has come to increase, perhaps double, the tuition fees paid from public funds to the universities which students attend, but recovering the cost from running budgets. Then universities will be competing tooth and nail for students.

Whether academics (or their union) welcome this development, it is happening and will continue. Nationally negotiated pay awards are bound eventually to disappear. It would be sensible to anticipate that certainty, if only for the sake of the greater say that academics would thereby acquire in the management of their own institutions. □

# Soviet Academy faces grass-roots revolt

- Academy's official candidates at risk
- Democratic fervour takes a hold

## Moscow

THE nomination conflict at the Academy of Sciences of the USSR is building up to a dramatic denouement this week — the academy's list of candidates may even be voted down by the academy's research institutes. The conference at which the academy will elect 20 of the 23 nominated candidates was scheduled for 20–22 March, at the Youth Cultural Centre in Moscow. The voters will be the 907 full and corresponding members of the academy and 440 institute representatives.

Since the January meeting at which Academicians Andrei Sakharov and Roald Sagdeev were voted down despite the recommendation of many institutes, ordinary scientists have seen the outcome as a blatant disregard of their opinions. After the protest meeting outside the academy on 2 February (see *Nature* 337, 593; 1989), several institutes formed a group to press for democratic elections.

Now the group has held a meeting of Moscow-region delegates to this week's electoral conference at which it was agreed to vote against all 23 official nominees unless the list is abrogated or enlarged (but enlargement is no longer possible). The Moscow region accounts for nearly half of all academy scientists.

The meeting emphasised that its intended "No" vote is not directed against particular nominees but is a protest against the "list imposed on the academy conference despite public opinion".

Even so, the outcome may be dramatic. Under the election rules, candidates who

fail to secure at least one vote more than half of the total eligible to vote will not be elected. If the number of successful candidates is fewer than 20, the conference will have to nominate further candidates on the spot, which is what the protesters want. Much will depend on the full and corresponding members of the academy, who will have a majority this week.

Will the academy bosses allow those with fewer letters after their names to carry the day? The answer cannot be simple. Not only the election is at stake, but the other issues triggered by January's nomination meeting, which in retrospect is the stone that started an avalanche of reforming public opinion in science.

Democratic reform is sweeping the academy. The procedure of electing institute, department and laboratory heads has been changed beyond recognition. Research groups compete for research grants, which is a novel development. Think tanks are set up for particular problems in research and development.

But the outdated is stubborn and tenacious, even though the backward-looking do not offer open resistance. Moth-eaten patterns of behaviour have inertia, and the research community is wary of risky ventures.

The protest meeting at which the decision was taken to vote "No" against the official list of candidates was also the first to voice a now-popular idea — that of creating an independent Soviet scientists' union. The praesidium of the academy supported this initiative at its meeting of 7 March, and appointed a working-group under Yuri Osipyan, an academy vice-president and director of the Moscow Solid State Physics Institute, to study the idea; a national researchers' conference is planned.

But the inter-institute activist group is in a ferment, regarding the academy's action as a means of appropriating its own project and of attaching the budding union to the praesidium.

At a rally of Moscow researchers which I attended on 11 March, the union's prospects were debated. Although the organizers had invited members of the academy's upper echelons, the bosses were conspicuous by their absence. The rally adopted the text of an address to Soviet scientists about the formation of the union, and elected an organizing committee with close on 40 members. An inaugural conference is expected in May.

*Nature Moscow correspondent/Novosti*

# Full sequence for *E. coli*

## Tokyo

JAPAN'S Ministry of Education, Culture and Science (MESC) will shortly announce its backing for a project to sequence the entire genome of the bacterium *Escherichia coli*. With luck, *E. coli*'s estimated 4,700 kilobase pairs, one thousandth the number of the human genome, could be sequenced in five years. Funding for the project will remain uncertain until the Diet passes the 1989 budget, delayed by political quarrels over the Recruit bribery scandal. But given the scale of MESC's 'priority areas of research' fund, it seems likely that more than a million dollars a year will be provided for an initial three years.

The project is led by Takashi Yura of Kyoto University and Katsumi Isono of

By July 1987, most of the *E. coli* genome had been cloned, as shown in the outer ring here. The bars represent unclosed regions and the inner two rings show the 'gaps' closed by successive clonings. Scale in kilobases from 0 min. the *thr* locus. (Modified from Y. Kohara, K. Akiyama and K. Isono, *Cell* 50, 495; 1987.)

Kobe University and builds on a physical map of the *E. coli* chromosome put together from 3,400 clones (see box). Researchers from Kyoto, Kobe, Osaka and Tokyo universities will make up the core of the project, but international collaboration should become possible once a clone bank has been established at the National Institute of Genetics at Mishima.

Of course, *E. coli* has already been extensively studied. More than 1,000 genes have been mapped and about 450 kilobase pairs have been sequenced by researchers around the world. Isono says he hopes his laboratory alone will be able to manage 200–500 kilobases a year. He adds a note of caution, however, because in sequencing projects, "90 per cent of the work is done in 50 per cent of the time", with unbridgeable gaps remaining.

If successful, the complete *E. coli* sequence will be the first for an independently living organism.

Moscow spring: thousands marched in Moscow in support of pro-perestroika Boris Yeltsin in Sunday's election.

# California may take hard line

## Berkeley

THE University of California (UC) is contemplating changes to its tenure policy for faculty members that would permit the removal of the "grossly incompetent". The new policy was approved by the Berkeley faculty senate last month; other campuses are considering adopting the same rules. Supporters of the new measure say it provides clear and specific criteria by which to judge faculty performance, specifying as it does dismissal rather than demotion for those judged incompetent.

US universities have been forced to tackle the issue of faculty competence, especially where older people are concerned, because federal law may soon prohibit compulsory retirement ages. Indeed, universities were exempted from the federal Age Discrimination in Employment Act of 1984, which made mandatory retirement illegal, and allowed to require retirement at 70, but that exemption will lapse in 1993 if not renewed by Congress.

Out of a general concern over "non-productive faculty", UC began in 1984 to review all tenured faculty members who had not appeared before a promotions or other committee for at least five years. During the first round of reviews, five people were found to be both creatively unproductive and grossly deficient in teaching.

While university rules allow that tenure may be terminated "for good cause", the

service to students". Faculty members whose five-year evaluations produced such a record would be offered counseling and assistance, such as retraining, says English professor Ralph Rader, who presented the proposal to the academic senate last month. Only if those failed would dismissal be considered.

The purpose of the proposal is to set up machinery for dealing with incompetence that is so formalized and specific, says Rader, that it will automatically be set in motion by a negative review. But he expects that most such findings would lead not to unconditional dismissal, but to negotiated early retirement.

## INTERNATIONAL RELATIONS

### Sierra Leone takes on the Soviet Union

#### London

THE Soviet Union is considering suing the Sierra Leone government for damages following the recent 8-day detention of the research vessel *Akademik Mstislav Keldysh* in the port city of Freetown.

The peculiar incident began last month when the oceanography research vessel, owned by the Academy of Sciences of the USSR, arrived in Freetown to pick up some representatives of a West German company that had recently completed repairs to the two deep-water submersibles carried on the ship. The plan was to test the repaired submersibles at sea 100 km west of Sierra Leone, where conditions are favourable at this time of year.

But when the ship docked at Freetown, it was boarded by Sierra Leone officials who removed the captain and several others, and questioned them in a local hotel. When the West Germans arrived in Freetown by air, they too were detained and questioned.

The Soviet foreign ministry immediately issued a strongly worded protest, calling the detention of the ship "a case of deliberate provocation". Soviet officials maintain that the Sierra Leone government was given 72 hours' notice of the ship's intention to dock at Freetown. Other countries, including Britain, whose scientists were also aboard the vessel, seemed less inclined to become involved in the dispute.

The Sierra Leone government has not explained why the ship was detained. According to the ship's captain, the Sierra Leone government evidently believed either that the ship was on a military mission, or that it was intending to dump toxic waste within Sierra Leone's territorial waters.

The ship was eventually permitted to leave, but the normally cordial diplomatic relations between the two countries are now strained.

Vera Rich

None of the five faculty members at Berkeley judged incompetent was close to retirement age, says Rader, who emphasizes that the policy is not age discriminatory. "The aim", he says, "is to deal with incompetence without reference to age."

Elizabeth Fader, of the American Association of Universities, says that concern over incompetence is rising at many universities, although most of the proposals for dealing with it have focused on incentives for early retirement, aimed at offsetting the ending of compulsory retirement ages. The National Academy of Sciences has begun a study, expected to be completed in two years, of the potential consequences for universities of the elimination of compulsory retirement.

## SOUTH AFRICA

### Kane-Berman wins reinstatement

#### Cape Town

DR Jocelyn Kane-Berman, who was dismissed as superintendent of Groote Schuur Hospital in November after naming Nelson Mandela as her choice of premier in a newspaper interview (see *Nature* 338, 4; 1989), has been reinstated in her post with immediate effect.

The Administrator of the Cape Province, Mr Gene Louw (under whose aegis hospital administration falls) said on 10 March: "I can merely say that I took the initiative to bring it about. I thought it was in the best interests of Groote Schuur Hospital." This complete change in the government's attitude seems to be related to an appeal by Kane-Berman to have her reinstatement ordered by the courts. She had already served papers on Louw and other provincial officials, and her case was due to be heard in the Cape Supreme Court on 20 April. In December, Louw described Kane-Berman's removal as "final from the outset", and last month in parliament the Minister of Health and Population Development, Dr Willie van Niekerk, refused to intervene.

Kane-Berman has now agreed to withdraw the legal proceedings, and agreement has been reached on costs. She has, however, retracted her comments in the weekend newspaper in which she made her "controversial" statement, and has tendered her apology towards those persons and offices that were embarrassed. It is rumoured that South Africa's ailing State President, P.W. Botha personally ordered Kane-Berman's removal, although this has been denied by government spokesmen.

Kane-Berman, who described herself as "quite delighted" by her reinstatement, said: "I'm very pleased that the matter has been amicably resolved." **Michael Cherry**

statement is so vague as to be worthless, according to UC Berkeley engineering professor Ernest Kuh, chairman of the committee responsible for the new proposals. But the new policy, he says, breaks new ground, and other universities may wish to follow.

Under the new proposals, a faculty member, to be judged incompetent, must have both "ceased to engage in serious scholarship or creative activity for a substantial period of time" and be teaching in a manner "so inadequate that it is a dis-

# Kansai science city takes root

## Kyoto

WITH the opening last week of a new advanced telecommunications research institute, the Kansai region of Japan took its first step towards building a massive \$25,000 million 'Science City' designed to challenge the Tokyo region's dominance in high technology.

The Kansai region, encompassing Kyoto, Osaka and Kobe, is a powerful force in the world economy. Its gross 'national' product is twice that of Australia or the Netherlands, and by 1992 it will have Japan's first 24-hour international airport, providing direct access to foreign capitals.

Tax concessions will encourage research and educational institutes to move to the city. But the intention is to avoid the mistakes made in Japan's last giant science city project at Tsukuba, an hour's ride from Tokyo. Tsukuba was created by relocating 46 government research institutes and two universities from cramped quarters in Tokyo to a undeveloped site. But the city's cultural amenities never caught up with its laboratories and many of its research personnel prefer to commute from Tokyo than to live among the paddy fields.

Kansai's science city is planning for slower and more dispersed growth that will integrate it into surrounding communities. And rather than government laboratories, its focus will be on the development of "the basic sciences and their combination with applied technology". To help towards this objective, an International Institute of Advanced Studies, modelled on those at Princeton and Aspen in the United States, and a new national library, to rival that at the Diet in Tokyo, were planned as early components of the city. The institute will be built alongside

Advanced Telecommunications Research Institute International (better known as just ATR), the first major new laboratory at the city site.

ATR, backed by private industry, the Ministry of International Trade and Industry (MITI) and the Ministry of Posts and Telecommunications, sees little challenge left in developing telecommunications to move information economically from one fixed location to another. Rather, the institute looks to the long-term basic research that will provide automatic translation telephones, totally portable communications systems making it possible to call "anyone, anywhere, at any time", and neural-network computers to provide friendly man/machine interfaces. The institute has begun work with 160 researchers and is expected to have 300 by 1995.

Two government-supported projects are likely to come to the city: a MITI Institute for Ion Engineering, and a Ministry of Education, Culture and Science (MESC) graduate study institute. The MESC institute will be Japan's second 'graduate university', designed to boost the comparatively low number of postgraduate students in Japan, provide graduate students for the research institutes which are not attached to universities and exercise MESC's newly approved right to accept industrial funding for university chairs.

Private-sector companies will provide the great mass of the research institutes. Land has already been set aside for 10 such institutes. Biotechnology may turn out to be a strong theme, given that more than half of all Japan's major biotechnology and pharmaceutical companies are based in Kansai.

## MICROCHIPS

# Britain bows out of hi-tech

## London

THE sale last week of Britain's microchip company, Inmos, best-known for its revolutionary transputer, to SGS-Thomson (ST), a semiconductor manufacturer formed by the Italian and French governments in 1987, could mean that Europe has a semiconductor group capable of competing with the world-leaders from Japan and the United States. But the loss of British control illustrates the unwillingness of the country's industry and government to take a longterm view of investment in technology.

Britain's only other microchip manufacturer, Plessey, is also likely to go from national control into the hands of the West German company Siemens and the British company GEC; the takeover is under review by the Monopolies and Mergers

Commission. The British government, after launching Inmos in 1978, sold it six years later, before it made a profit, to the entertainments group Thorn EMI. But Inmos was seen as a high risk for the lighting and television rental group, making profits last year for only the first time since the beginning of the 1980s.

There were fears of redundancies in the three main Inmos plants, which employ over 1000 people, but a spokesman for the company says that ST plans to increase investment in the company, making Britain the headquarters of its microprocessing capability and possibly creating more jobs. For the sale of Inmos, Thorn EMI receives a 10 per cent shareholding in ST, and will continue to obtain the revenue from some patents on Inmos technology.

Christine McGourty

## Technology transfer

THE transfer of technology from universities and national laboratories into industry receives less government support in Britain than in West Germany, France and Japan, despite the relatively low industrial investment in research and development in Britain which makes technology transfer more important, according to a report published last week by Britain's National Economic Development Council. The report compares efforts at technology transfer in Britain, the United States, Japan, France and West Germany. Britain's efforts compare badly with those of its competitors. The report says that British companies are reluctant to take up external technology and do not view technology as a long-term asset.

C.McG.

## Radioactive waste

THE choice of sites for a deep repository for low-level and intermediate-level radioactive waste in Britain has been narrowed down to two: Sellafield in Cumbria and Dounreay in Caithness. Both are already the sites of nuclear installations. After permission is obtained from the planning authorities, geological investigations will determine which site is chosen. United Kingdom Nirex Limited, which is responsible for the disposal of low- and intermediate-level radioactive waste says each repository could cost about £3,000 million and should be in operation by 2005.

C.McG.

## Language schism

ANATOL Sarokin, a geologist with the Byelorussian Hydrogeological Survey, has been threatened with dismissal for insisting on his right to use the Byelorussian language for his field notes and reports. His superiors say that only Russian may be used at work, but Sarokin maintains that as it is a Byelorussian survey, reports should be in Byelorussian — particularly at a time when so much emphasis is being publicly put on the fact that the Byelorussian Republic is 'bilingual'. But the directors of the survey say that reports must be in Russian because a copy has to be sent to Moscow, and they cannot afford to have them translated. Sarokin's case has been taken up by the weekly *Litseratura i Mastastva*, the main advocate of *perestroika* in the Byelorussian Republic.

V.R.

## Greenpeace recognized

THE Baltic Marine Environmental Protection Commission, established in 1980 by the governments of the seven littoral states (Denmark, Sweden, Finland, the Soviet Union, Poland and East Germany and West Germany) has changed its statutes to give observer status to the non-governmental group Greenpeace. At its regular meeting in February, the commission also resolved to set up an early-warning system for incipient environmental disasters; each participating state will warn the others if it observes unusual and disquieting phenomena in the marine environment.

V.R.

## Canada's NASA

CANADA finally has a space agency. After months of squabbling over where it should be located, the government announced earlier this month that the new agency's headquarters would be in the greater Montreal area. Until now, responsibility for Canada's space activities fell to many ministries. The decision to base the new agency in the province of Quebec ends a political battle between predominantly French-speaking Quebec and the predominantly English-speaking Ontario that held up plans to establish the agency. In addition to coordinating Canadian activities on the space station, the agency will manage RADARSAT, a planned Earth remote-sensing satellite, MSAT, an advanced communications satellite, and the Canadian astronaut office. The current fiscal year's space budget is C\$120 million, rising to C\$150 million next year.

Larkin Kerwin has resigned as president of the Canadian National Research Council to become president-designate of the new agency. J.P.

## President removed

DR Pulat Khabibullaev, nuclear physicist and former president of the Uzbek Academy of Sciences, has been replaced as president of the Uzbek Republic on the grounds of corruption. He was accused of having "actively assisted" the scientific careers of close relatives of now-disgraced local party leaders, procuring them posts for which they were insufficiently qualified and which they treated as virtual sinecures. Furthermore, he is said to have used his position as vice-president and then president of the academy to have his name attached as co-author to no fewer than 322 scientific papers to which he had contributed nothing. Called to account before the bureau of the Central Committee of the Communist Party of Uzbekistan, Khabibullaev made a formal self-criticism, whereupon the Party recommended that he be allowed to resign as president of Uzbekistan and "transferred to scientific work". V.R.

## Fang speaks out

DR Fang Lizhi, the Chinese astrophysicist and dissident who was prevented by the police from attending US President George Bush's banquet in Beijing, has not let the incident pass unchallenged. At a press conference at his home the following day, he suggested that the reluctance of the Chinese leadership to have dinner with one dissident on one single occasion must surely raise doubts about their "promised tolerance" of the future presence of non-socialist Hong Kong in post-1997 China. Official Chinese spokespersons continue to attack the original invitation as "disrespectful" to the president's official hosts — the Chinese leaders — and US reaction to Fang's exclusion as "irresponsible". V.R.

# Outside influences resented

## São Paulo

SOUTH American government officials promised at a series of meetings last week to respect the rain-forest environment while promoting development, and called for more research on the damage to rain forests. But a concurrent scientific meeting on rain-forest ecology dismissed these promises as mere rhetoric, and complained that researchers are being denied resources.

The foreign ministers of Ecuador, Brazil, Colombia, Venezuela, Peru, Surinam, Guiana and Bolivia gathered in Quito, Ecuador, last week for the third meeting of the Amazonian Cooperation Treaty, signed in 1978 to defend the region's environment. The ministers favour "rational" use of Amazonian resources, and condemn "any foreign interference on the policies and actions that the Amazonian countries make in the region".

The governors of several Brazilian states were in Manaus to discuss the newest federal environmental protection programme called "Nossa Natureza" ("Our Nature"). Announced last year as a response to growing internal and international criticism of rain-forest devastation, the programme consists of legislation strengthening forestry and mining codes and creating new protected areas. Brazilian President Jose Sarney is due to sign these measures on 6 April.

But scientists from INPA — Instituto Nacional de Pesquisas da Amazonia (National Institute of Amazon Research) — think otherwise. They feel left out of the planning of "Our Nature" and fear that it is going to be just another meaningless declaration of good intentions. Researchers from the institute held a last-minute "alternative" meeting on 7 and 8 March in Manaus to draft a response to the "Our Nature" approach, but were prevented from presenting their conclusions to the governors meeting nearby.

Brazilian Minister for Industrial Development, Science and Technology, Roberto Cardoso Alves, said in February that the rain forest is "practically intact", with just 1 per cent destroyed. Estimates from INPA put the figure at 8 per cent.

If governments are resisting foreign intervention, the same cannot be said for researchers. INPA has many foreign scientists, mainly US and German. One US scientist, Philip M. Fearnside, has become the institute's media star, by his constant advocacy of preservationist measures. He complains that red tape is drawing away many researchers from the Brazilian side of Amazonia: there are stories that some foreign scientists have had to wait a year for a visa to visit Brazil.

INPA researcher Muriel Saragoussi says the institute may lose more than a

third of its 284 researchers if a government decision to dismiss all public servants with less than five years on the job takes effect. The proposed layoffs are a result of a January economic plan by the federal government to try to stave off hyperinflation. Another consequence of this plan is a reduction of 50 per cent in the financing of research institutes.

Research on rain forests will certainly be an important part of the planned International Geosphere-Biosphere Programme (IGBP). The programme's executive director, Thomas Rosswall, toured last week through several Latin American countries to promote the programme. He diplomatically stated in São Paulo that Brazil has sovereignty to decide what to do with its natural resources, but added that all countries will have to take responsibility for what happens to the world's climate. He compared the situation of the rain forest with the emission of sulphur dioxide by Britain; only when scientists showed that British emissions were polluting Europe did the British government take measures to curb them. Brazil may face similar pressure when the true importance of the rain forest to global climate change is conclusively shown. IGBP is likely to place one of its proposed global observatories in the Latin American rain forest. Ricardo Bonalume Neto

## Mercurial approach

### São Paulo

THE Brazilian government has been somewhat mercurial in its approach to science and science policy. Two months after deciding to abolish the Ministry for Science and Technology, it announced last week that it was creating a new, cabinet-level Special Secretary for Science and Technology. The two-month-old Ministry of Industrial Development, Science and Technology, which emerged in the wake of the departure of the four-year-old science ministry, now becomes the Ministry for the Development of Industry and Commerce.

Critics say this confusion of names and ministries underlines the lack of a coherent policy for Brazil's scientific development. Nevertheless, the Brazilian Society for the Advancement of Science praised the creation of the new secretaryship. The society lobbied intensely to recreate the ministry in order to have a single entity to coordinate science policy.

Financial problems for science persist. Some ministry institutes now in the new secretary have less than half the money they need to function. Researchers at the National Institute of Amazon Research (INPA) have to buy fuel for their jeeps out of their own pockets. Ricardo Bonalume Neto

## UK UNIVERSITIES

## AUT exam boycott enters week 11

London

THE end of the 10-week-old lecturers' boycott of British university examinations is no closer after weeks of intense negotiations between the Association of University Teachers (AUT), the Committee of Vice-Chancellors and Principals (CVCP) and the government. If the action continues, final year students may not be awarded classified degrees, and universities fear students may take legal action against them. Already mid-term examinations have been cancelled and summer papers are not being prepared.

The CVCP is meeting this week to discuss how to minimize the effects of the strike on students. Vice-chancellors could decide to award unclassified degrees based on tutors' reports or to ask students to sit examinations after the summer, at the time when re-sits are usually taken. Meanwhile, they are hoping that AUT members will disagree with the council, the policy-making body of the union, which last week rejected the CVCP's latest offer of a pay rise. Members will be balloted in April on whether to accept the council's decision.

The offer of an increase of 6.5 per cent for 1989-90 was made after the universities received an undisclosed sum from the government, on condition that the strike is ended. The CVCP had asked for £187 million but received "a lot less than that", according to a spokesman. The union is certain that the universities can finance a larger pay increase, though Sir Mark Richmond, chairman of the CVCP, denies this, saying that the latest offer is final, and that to offer any more would bankrupt some universities.

Christine McGourty

## THINK-TANK

## Berlin academy fights closure threats

Munich

THE new left-wing government in West Berlin plans to close the 'Academy of Sciences and Technology in Berlin'. The academy was founded in 1987 by the then-conservative government as an interdisciplinary think-tank especially concerned with problems of technology and society. The Greens and Social Democrats now in power denounced the academy as an "old men's debating club" (see *Nature* 329, 659; 1987). The academy's research fields include solar energy, ageing and society, and the impact on German science of the exodus of researchers from Berlin in 1933. It had a 1988 budget of DM8 million, mostly provided by the West Berlin government.

The academy will fight for its existence. Spokesman Eberhard Vogt said that the "last word" had not yet been spoken about the future of the academy.

Steven Dickman

## DEFENCE RESEARCH

## Independent agency for UK

London

BRITAIN'S main defence research institutes are to be grouped together in an independent defence research agency in order to loosen their ties with the Ministry of Defence, their main customer.

At first the agency will be made up of four institutes: the Admiralty Research Establishment, the Royal Aerospace Establishment, the Royal Armament Research and Development Establishment and the Royal Signals and Radar Establishment.

The Aeroplane and Armament Experimental Establishment is also being considered, but the Chemical Defence Establishment (CDE) at Porton Down will not be part of the agency. A review carried out last year by a study team for the Ministry of Defence (MoD) said that, because of the political and public sensitivity about the work carried out there, and because of the role of the establishment in providing support to government on international arms control, the CDE should be excluded from the agency.

The agency will be expected to increase the work at the institutes carried out for industry, and will have to compete with industry for some contracts for the MoD. There is also likely to be a reduction in staff and in the number of sites. More than

12,000 staff work in the institutes at over 100 sites, most of which are in South-East England where land sales would be remunerative.

There are still many uncertainties surrounding the form of the new agency. A team has been set up to plan in detail the changes before the agency is formed in 1991. It could take the form of a trading fund within or outside the civil service, or it could be a government-owned public limited company. Full privatization has been ruled out.

Manpower is one of the important problems to be tackled. A serious shortfall in recruitment of young graduates, especially in electronics, computing and mathematics, combined with a high rate of resignations among the youngest and brightest of researchers, has led to a shortage of high-calibre staff. The defence research study team said that this could be solved by the introduction of more short-term contracts and by giving the agency more independence to fix pay scales, now set at civil servant rates.

The study team also stressed that in a new agency mechanisms must be put in place to safeguard strategic research, which could be neglected in the commercial climate.

Christine McGourty

## US SALARIES

## Less pay means empty jobs

Atlanta

THE AIDS epidemic may have helped the budget of the US Centers for Disease Control (CDC) to multiply to more than \$1,000 million a year in the past six years, but the hefty increase has not meant salary rises for its researchers.

Instead, the agency, the front-line of defence against epidemics in the United States which also helps to staunch outbreaks of disease around the world, is suffering from the same problems as the rest of the US government's research enterprise — those of hiring the best and the brightest talent.

Earlier this year, CDC's largest research centre, the 1,000-staff Center for Infectious Diseases, was forced to cast its net outside the United States to fill one of its top posts. Fred Murphy, director of the centre, made the unusual move of hiring one of Britain's top virologists, Brian Mahy, away from his directorship of the Agriculture and Food Research Council's Pirbright Laboratory. Five US scientists offered the job had turned it down because the \$75,000 salary was too low.

Mahy says he was not actively looking for a job when Murphy came knocking on his door, but recent shake-ups in the organization of British veterinary science (see

*Nature* 338, 191; 1989) made moving to the United States more attractive. He says he considered the CDC post an advancement and it offered him a 25 per cent raise in salary. Several other Pirbright scientists left with Mahy to work at CDC.

CDC's Murphy says he spends much of his time looking for prospective employees, and that it takes 6-12 months to find the right people for executive-level positions within his office and as directors for his centre's 12 divisions. He has had to fill seven "very senior positions" within the past year and half.

The most pressing vacancy at CDC is a replacement for CDC director James O. Mason, who has been chosen by the Bush administration to be the US Assistant Secretary of Health, in charge of the Public Health Service which oversees both CDC and the National Institutes of Health. While Mason or the new Secretary of Health and Human Services, Louis Sullivan, could turn the CDC directorship into a political appointment, George Hardy, acting deputy director of CDC, predicts that the job will be filled by a search committee, a process which could take several months. Mason is sure to take an active interest in selecting the new CDC director.

Carol Ezzell

# Fears of drought assuaged

## Berkeley & Boston

A MODERATELY wet winter has eased fears of a second year of drought in much of the mid-west and Rocky mountain areas of the United States, and long-range forecasts have even raised hopes of a year of bumper crops. But some regions still face shortages, and despite recent rains, rationing is already being implemented.

Last season's mid-western drought was probably a one-time occurrence, possibly caused by temperature anomalies in the tropical east Pacific. While some areas of the mid-west remain drier than normal, another extensive grain-belt drought is unlikely this year.

Californians now face an unprecedented third consecutive year of drought, as weather patterns in the Pacific diverted the jet stream and its storms away from the state for much of the season. Rainfall for most of the winter was less than half of normal, leaving the state in a dangerously dry condition, according to William Helms of the state drought centre. A wet March has provided some relief in the central part of the state, and the cities of Southern California were spared the full effects of the drought, but much of the San Francisco Bay area is still in crisis and beginning to bargain for water from other parts of the state.

Many Californians assumed the drought could not persist for three years in a row, as it never has in the 120 years during which records have been kept. So the current crisis, with its accompanying water rationing, came as a rude shock. Santa Clara County, home to California's semiconductor industry, is one of the hardest hit areas in the state. Dependent on local water supplies, the county has been little helped by the March rains, which fell mostly to the north and in the mountains to the east.

Reservoirs that feed Santa Clara's underground aquifer were empty in February for the first time in history, sending county officials begging for water loans from other parts of the state, amid fears that land in Santa Clara would begin to sink if more water were drawn from underground.

March rains have eased the plight of California's \$15,000 million agriculture industry, which earlier this season was warned of likely cutbacks in water allotments of up to 60 per cent. The State Department of Water Resources says cutbacks are still likely, but will be smaller.

In the north-east, the unseasonably warm and dry winter has also prompted concern over the prospect of severe water shortages. Water levels in key reservoirs in New York, Massachusetts and several other states are at or near historic low points, after four consecutive years of

abnormally arid weather in the region.

Last week, New York's Drought Management Task Force voted unanimously to recommend that a water emergency be declared for New York City and 11 other counties in the state. The move followed a declaration of water emergency last month in Massachusetts, giving the state government jurisdiction to enforce mandatory restrictions on water usage by municipalities.

Although the situation is most severe in Massachusetts and southern New York, representatives from the United States Geological Survey (USGS) and other state environmental agencies say that all the northeastern states in the United States have been affected by particularly dry conditions over the past year and

many areas in the region are threatened by drought.

In Massachusetts, the declaration of a water emergency came after reports from the Water Resources Authority that the state's largest reservoir, serving more than 40 municipalities, had dropped to its lowest level in 15 years. Similarly, reservoir levels in New York stand at only 55.9 per cent of their capacity, more than 30 per cent below the average for this time of year. Because Massachusetts and New York have had almost no snow this year, state water officials are concerned that the spring thaw will not provide nearly enough water to replenish the system.

The problem in Massachusetts is intensified further by water contamination at some local sources which has forced several municipalities in the state to close their local water supplies.

## SOVIET PSYCHIATRY

# New independent association

## London

NINETEEN Soviet psychiatrists, from Moscow, Leningrad and other major cities, have established the Independent Psychiatric Association (IPA) of the USSR. According to Dr Viktor Lanovoi, president of the new organization, the IPA does not intend to enter into conflict with the existing All-Union Society of Neuropathologists and Psychiatrists. Nevertheless, its founding statement makes it clear that it has come into being in response to the abuses that have compromised Soviet psychiatry in the eyes of the world.

Its founding statement declares that the IPA is open to "all those who consider it necessary . . . to defend the doctor against social and political pressure, and to defend people, healthy or ill, against extreme socio-political and psychiatric arbitrariness".

The IPA founding follows hard on the heels of a two-week visit to the Soviet Union by a team of US psychiatrists to investigate charges of psychiatric abuse. International criticism of Soviet psychiatric practices resulted in a decision in 1983 by the All-Union Society of Neuropathologists and Psychiatrists to resign from the World Psychiatric Association (WPA) to forestall its impending expulsion. The society has now filed an application for readmission, but the IPA has announced its intention to apply to the world body as well, and only one national society in each country can be a member of the WPA.

The US visiting delegation was allowed into the Soviet Union under conditions similar to those governing arms-control inspectors. It visited hospitals and patients of its choice. IPA member Aleksandr Podrabinek, who some 10 years ago

became the first person within the Soviet Union to attempt to monitor psychiatric abuse, worked closely with the delegation. Podrabinek maintains that recent, much publicized "improvements" in the Soviet treatment of penal psychiatric cases were largely cosmetic. Moreover, rather than releasing all political "patients", Podrabinek points out, the authorities have actually hospitalized some new ones.

Nevertheless, Podrabinek welcomed the US visit as an important breakthrough. Now back in the United States, the visiting team will issue an executive summary of its findings in one month. The American Psychiatric Association, one of the trip's organizers, has taken no position on the All-Union Society's application for readmission to the WPA, and will not comment until the report is produced. But Podrabinek has issued his own account. He stressed the shock felt by many of the Americans at the lack of compassion with which the Soviet psychiatrists treated their political "patients".

Although the Soviet psychiatric establishment clearly needs to win over world opinion, and in particular that of the powerful US vote in the WPA, official opinions, according to Podrabinek, were divided as to whether the proposed US visit would do them more good than harm. Up to the last minute, he said, the Soviet side kept altering the terms of the visit — deciding, for example, that the Soviet psychiatrists and not the patients nor the Americans would select which relatives or friends would accompany the patients during the examinations. In the end, the patients simply brought the relatives of their choice, and the Soviet side made no attempt to challenge these choices.

## NUCLEAR POWER

# Holy river no obstacle

New Delhi

IGNORING protests from environmental groups, India last week commissioned the controversial nuclear power reactor at Narora on the banks of the sacred Ganges in the state of Uttar Pradesh, 140 km east of Delhi.

The 230-MW reactor is the first of two units at India's fourth nuclear power station. Commissioning of the second unit at Narora has been put off until 1990 because of a lack of indigenous heavy water.

The twin reactors of the \$500-million Narora Atomic Power Station (NAPS) are based on the Canadian CANDU design that uses natural uranium fuel and heavy water as moderator and coolant. After Canada severed nuclear ties in 1974, India on its own built two CANDU at Kalpakkam near Madras in 1985. NAPS is the second totally indigenous station and, like the Madras reactors, is outside the control of the International Atomic Energy Agency (IAEA). The two US-built boiling-water reactors in Tarapur near Bombay and the two reactors near Kota in Rajasthan, built by Canada, are under IAEA inspection.

The siting of the new power station at Narora has been the subject of a bitter controversy between the Department of Atomic Energy (DAE) and environmental groups such as the Committee for Sane Nuclear Policy (Cosnup). While the Tarapur and Madras stations are sited near the sea, and the Kota reactors use cooling water from a lake, NAPS is the first Indian nuclear plant to be built near a major river. Although only make-up water will be drawn from the Ganges for the closed circuit cooling system, treated effluents will drain into the river, which is currently being cleaned up under a \$250-million 'Ganga action plan'.

Environmental groups have organized a 'Save Narora' campaign that is concerned about possible radioactive pollution of the Ganges, the life-line for 200 million Indians living in its basin. The new reactor at Narora is also the first reactor in India to be located in a seismic zone. Critics say the risk of radioactive pollution of the Ganges is heightened by the fact that the reactors are standing on alluvial soil only 50 km away from the Moradabad Fault which was the centre of an earthquake in 1956.

These fears have been dismissed by DAE, which says the reactors have double containment systems and have been designed for automatic safe shutdown in case of earth tremors. The effluent treatment will be such that there will be 'zero-radiation discharge' into the Ganges. Critics, unconvinced, note that the extra money spent on making the plant earth-

quake-proof could have been saved by siting the plant elsewhere. Earthquake-proof design considerations were mainly responsible for cost and time overruns. NAPS took 12 instead of 7 years to complete and its cost had doubled.

Ironically, commissioning of the new reactor at Narora will not add to India's installed nuclear power capacity but only bring it to the level that existed in 1986. Since then, output from the Tarapur reactors has been deliberately reduced to lessen the radiation dose to personnel there, and one of the two Kota units has been shut down due to a leak from the end plate of the reactor vessel. Attempts to plug the leak permanently have so far failed.

By the year 2000, India plans to produce 10,000 MW or 10 per cent of total electricity demand from nuclear reactors. This would require commissioning of two or three reactors per year, an impossible task. Even if DAE could mass-produce reactors, it has to face a growing anti-nuclear lobby.

Opposition is already mounting against the nuclear station under construction at Kaiga, in the midst of rain forest in western Ghats, and the two 1,000-MW reactors proposed to be built by the Soviet Union at Kodangulam on east coast of south India.

K. S. Jayaraman

## Soviet citizens not impressed by IAEA

London

PLANS for a nuclear power and heating station in Gor'kii in the Soviet Union have roused considerable opposition from local inhabitants, who, in the aftermath of the Chernobyl accident, are concerned at the proposed siting of such a station only a few kilometres from the city centre. The Soviet nuclear planners have now agreed to call in experts from the International Atomic Energy Agency (IAEA) in Vienna, to assess the safety aspects. If the IAEA gives its approval, the station could begin supplying the city with heat next summer.

Twelve such stations were originally planned for the European part of the Soviet Union, with Gor'kii as the prototype. But the partly built station at Minsk is already being modified to operate on conventional fossil fuel, under local pressure. And Soviet public opinion, it seems, is not always ready to accept the IAEA experts as disinterested parties. Last autumn, when Dr Murray Rosen of IAEA tried to assure local people that the RBMK (Chernobyl-type) power station at Ignalina posed no threat, he received boos and catcalls.

## CRAFOORD PRIZE

## Pioneer in rocketry and radiation discovery

Washington

THIS year's Crafoord Prize has been awarded by the Royal Swedish Academy of Sciences to James Van Allen of the University of Iowa.

The prize, worth about \$250,000, is given annually in an area not covered by the Nobel prizes. This year's recipient is cited for his work in magnetospheric physics, his best-known accomplishment being the discovery in 1958 of the 'Van Allen' belts, regions in the upper atmosphere in which charged particles of solar origin are trapped by the Earth's magnetic field.

Van Allen began his scientific career as an experimental nuclear physicist and became a pioneer of scientific rocketry, designing both novel detectors and the rockets that carried them. The Aerobee rocket was his work, and he was chief scientist for the Explorer I satellite, which found the radiation belts that carry his name. At the University of Iowa in the early 1960s, he and his pupils designed and built an important series of satellites.

These days, Van Allen is known as a critic of manned space exploration, believing it to be a scientifically unproductive extravagance.

David Lindley

## FOSSIL LOSS

## Tourism falls victim to 'Tyrannosaurus'

Tokyo

JAPAN's only fossil to have acquired the exalted status of a national 'natural treasure' was toppled from its perch last week when word finally reached the press that the carnivorous *Tyrannosaurus* dinosaur discovered in 1976 at Mikasa City, Hokkaido, is actually a lizard, *Mosasaurus*.

Doubts about the fossil's identity have been circulating privately in the Japanese geological community for some time. Now that the truth has come out from the National Science Museum's Ikuo Obata, who made the original misidentification, Mikasa City (population 20,000) is stuck with a massive concrete replica of an erect *Tyrannosaurus*, a thriving industry supplying *Tyrannosaurus* souvenirs — from key rings to sweets and pickles — and a museum containing the fossilized head of what, after all, is a *Mosasaurus*.

City officials are deeply disturbed, saying that the *Tyrannosaurus* business is all they had to stop the outflow of people to big cities. The Cultural Agency, which granted the 'natural treasure' title says it is "studying the situation".

Alun Anderson

## Reprints still in demand

SIR—Following on the discussion on reprints (*Nature* 336, 708; 1988) I should like to raise two points that very much concern a minority of workers like myself.

First, as a full-time school teacher who has a reasonable output of papers and whose place of employment is not in a university or professional laboratory, I rely on reprints to keep me abreast of my subject. To start with, I rely on a small nucleus of workers who automatically send me reprints of relevant papers. From those, I can then follow up what seem to be useful references by sending for more reprints. I do not have access to abstracting systems nor to libraries that stock journals except on the rare occasions when I make the journey to London.

Second, as an isolated entomologist, I become aware of others with an interest in my field only by receiving reprint requests.

I would be very sad indeed if Ivor Smith's attitude started a widespread movement away from the reprint system.

J.T.C. SELICK

*The Common Room,  
Uppingham School,  
Uppingham,  
Rutland LE15 9QE, UK*

SIR—Ivor Smith expresses his discontent about the reprint requests he received for his two-page paper, all of which he ignored. He claims that "the European reprint is a disappearing commodity". I believe this attitude is detrimental to at least one part of the scientific community and is inconsistent with efforts to improve cooperation and exchange of information between scientists in the West and East (*Nature* 337, 1; 1989).

I have recently received 153 requests for a one-page paper, 90 of them from countries where neither photocopiers nor scientific journals are abundant. I myself worked for five years in an institute of the Czechoslovak Academy of Sciences. The institute was well equipped and financed and theoretically one could get any paper, but it could take weeks or months, depending on the availability of the journal. It was not possible to order all the papers one wanted that were not available in the library — the capacity of the service would have been far exceeded. Bureaucracy and censorship made things even more complicated: for example, issues of *Nature* were sometimes incomplete. One had to order a copy of a specified article and sign a declaration that the copy would be used only for scientific purposes. Such measures will vanish with the general political shift, but the availability of the scientific literature will not improve significantly in the near future. Reprints remain an important source of information for researchers in the Eastern bloc.

Ivor Smith uses the difference between the cost of postage and that of a photocopy as an argument against reprints. Such reasoning is inappropriate for scientists in the Eastern bloc: as money for postage is limited, some workers pay for this service themselves. This is necessary especially in fast-evolving fields or where more than one field has to be pursued simultaneously.

The decision whether or not to answer a request is a personal one. It depends also on postal funds available. Nevertheless, there is a consensus in the scientific community that reprint requests should be answered. Not to do so is unfair to those who conform — journals that provide authors with free reprints and researchers who ask for them. I suggest, therefore, that authors who cannot or do not intend to send out reprints make an arrangement to spare others the unnecessary costs: as a part of the corresponding address (in order to be included in indexing periodicals such as *Current Contents*), a note "no reprints" should be inserted. This could also serve as a hint for the journals in question to save the costs of producing free reprints.

PETR KARLOVSKY

*Abteilung für Molekulare Genetik (GSF),  
Grisebachstrasse 6,  
D-3400 Göttingen, FRG*

SIR—If one wants a copy of a recent paper that has photographs showing ultrastructural detail (common in microscopy and biology journals), then a photocopy is usually not good enough.

PATRICIA A. MOSS

University of Manchester Institute of  
Science and Technology,  
PO Box 88,  
Manchester M60 1QD, UK*

## Sadly confused

SIR—Frank W. Dobbs' criticism (*Nature* 337, 497; 1989) is sadly correct, as you noted, but he is sadly mistaken on who was confused: it was Kepler who analysed Tycho's measurements and not Copernicus who analysed Kepler's — to wit: Copernicus 1473–1543, Tycho 1546–1601, Kepler 1571–1630.

KLAUS SANDER

Institut für Biologie I (Zoologie),  
Albertstrasse 21 a,  
D-7800 Freiburg,  
FRG*

Letters submitted for Correspondence should be typed, double-spaced, on one side of the paper only. □

## African birds

SIR—Tim Crowe's diatribe (*Nature* 338, 11–12; 1989) on the seventh Pan-African Ornithological Congress (PAOC) left me wondering if we had actually attended the same event. I did not think I was alone in finding it a highly enjoyable, well-organized and scientifically stimulating conference which could also (for the first time, it seems) honestly be described as 'pan-African' in its representation.

It is possible to understand Crowe's frustration over the processing of his and his colleagues' visas. But his obsession with the so-called 'exclusion' of South Africans prevents him from grasping the fact that the future of African ornithology depends on our building a basis for it over the entire continent. In this regard, his dismissal of the papers given by African delegates is particularly unhelpful (not to say offensive). Unfortunately, few African ornithologists will have had access to resources and training of the calibre provided by a FitzPatrick Institute. This makes it all the more important that young scientists have the chance to attend international conferences such as this one, where they can present work, receive constructive criticism and learn from the example of their more experienced colleagues. Indeed, this is one of the best reasons for the congress's new regionalism. The fact that last year's meeting was held in East Africa allowed many scientists to attend who would otherwise never have had the chance, and at future congresses this opportunity will be extended to those in Central and West Africa as well.

Crowe's nostalgia for the days when the PAOC was run by South Africans for South Africans is profoundly unrealistic. I doubt that the absence of many distinguished South African ornithologists can have cheered any delegate to the seventh congress, even among the supposedly "virulent anti-South African elements". But this situation clearly arose as a result of the distortions induced by apartheid, distortions which, while they act to impoverish African science, cannot simply be ignored. The cost of guaranteeing South African participation in all future congresses would be the continued paralysis of pan-African ornithology, and the seventh PAOC decided that this cost is too great. Eventually, the isolation of South African ornithologists must be ended through political change. In preparation, Crowe's colleagues would do well to follow the positive steps outlined at the end of his article — in particular to remedy the disgraceful lack of black South Africans among their number.

# Novel materials from theory

Marvin L. Cohen

The structures of crystals can be predicted using information about their chemical composition as the only input. Such approaches will greatly aid the search for new materials.

THE "continuing scandal" referred to by John Maddox in his recent article "Crystals from First Principles"<sup>1</sup> is "that it remains in general impossible to predict the structure of even the simplest crystalline solids from a knowledge of their chemical composition". If the words "in general" are intended to mean for all cases of simple crystalline solids, then the statement is certainly true. But for some cases, the implied goal has already been achieved; some of the approaches used strongly resemble what Maddox feels "ought to be possible".

Silicon is probably the best example. At atmospheric pressure and at room temperature, silicon is a tetrahedrally coordinated semiconductor with the diamond structure. In 1980, M.T. Yin and I showed that starting with the atomic number of silicon, 14, a precise estimate of the total energy of solids can be generated composed of specific arrangements of silicon cores of charge +4 embedded in a sea of itinerant valence electrons<sup>2</sup>. A core contains the silicon nucleus and ten tightly held 'core' electrons, which are assumed to be unchanged in going from the atomic to solid state. The four valence electrons from each atom are free to wander throughout the crystal and are expected to arrange themselves in a manner that achieves a minimum energy state. So, for an assumed crystal structure, the total energy of the core and valence electrons could be computed as a function of the core separation, or volume per unit cell.

The next step is that anticipated for future calculations by Maddox. A list of good candidate structures is used to choose various arrangements of the cores, and their energy is compared for many assumed volumes. In the original study<sup>2</sup> on silicon, seven structural phases are examined (see figure). These are diamond, hexagonal diamond, white tin ( $\beta$ -tin), simple cubic (sc), body-centred cubic (bcc), hexagonal close-packed (hcp) and face-centred cubic (fcc). Several more structures have been considered since 1980. As shown in the figure, the diamond structure was computed to have the lowest energy among these for the volume appropriate for atmospheric pressure. The minimum of the curve of energy versus volume for the diamond structure gives the lattice constant and its curvature yields the compressibility or bulk modulus. The calculated results agreed with experiment to within 0.4 per cent for the lattice

constant and 1 per cent for the compressibility, which is impressive considering that the input is only the atomic number and the list of candidate structures.

This calculation gives a starting point for Maddox's goal that, by the use of a powerful computer, a chemical formula is typed in to "obtain, as output, the atomic coordinates of the atoms in a unit cell". In fact, for silicon even more has been done.

Total energy curves of seven structural phases of silicon as a function of volume normalized to the volume of the diamond phase. The dashed line, which is the common tangent between the diamond and  $\beta$ -tin phase, represents the path for this pressure-induced structural transition. Its slope gives an estimate of the transition pressure. (From ref. 2; see text for further details.)

When the atomic mass was added to the input information, the vibrational spectrum, the electron-lattice interactions, anharmonic lattice couplings, cohesive energy and other properties, together with their pressure dependence, were obtained. But most of these properties were known beforehand. Despite the first-principles nature of the calculation, its success does not completely meet Maddox's challenge — "the goal of calculating from first principles the crystal structure of a compound of which nothing is known except chemical composition".

But examination of the work on silicon again shows that, to a large extent, even this goal has also been achieved. Although the calculation described above demonstrates that diamond is the structure of

lowest energy at atmospheric pressure, its energy increases above that of some other structures as the volume per atom is reduced, which can be achieved in the laboratory by subjecting a sample to pressure. The reduced-volume calculation showed that silicon should be metallic and stable in the white-tin structure at pressures around 100 kilobars and in the hexagonal close-packed structure at 400 kilobars. The path for the diamond to white-tin pressure-induced transformation is shown by the dashed line in the figure. This line is the common tangent between the curves, and the points labelled 1, 2, 3 and 4 represent volumes at which the solid (1) is the diamond structure, (2) is beginning the transition, (3) is ending the transition and (4) is in the white-tin structure. The calculated values of the transition volumes at (2) and (3) are within 2 per cent of their measured values. Using the slope of the common tangent, the transition pressure for the transformation was calculated and it is within several per cent of the measured values. The white-tin transition was known, but the hexagonal close-packed structure was a mere prediction. Experiments were done, and the predicted structure was found at the estimated pressure. The lattice constant and many other properties were also predicted successfully. Another simpler hexagonal structure appeared at lower pressures, and the theory was used to compute its properties.

When the calculations were extended to calculate the lattice vibrational properties and the interactions of the valence electrons with the vibrating core, there was enough information to predict that simple hexagonal silicon should be superconducting at temperatures in the 5–10-kelvin range and that hexagonal close-packed silicon would superconduct around 4–5 kelvin. The predictions were verified<sup>3,4</sup>, as was the pressure dependence of the transition temperature.

So there is an example of a successful prediction of the existence of high-pressure structural phases, their lattice constants, electronic and lattice properties, and even superconductivity. The calculation proceeds from first principles and requires only the atomic numbers, atomic masses and candidate structures as input. Silicon is the prototype material, but many systems have been studied with similar success. For example, the simple hexagonal structure of germanium was success-

fully predicted to exist in the 800-kilobar range. Other materials that have been investigated include metals, III-V semiconductors and some ionic insulators. Maddox discusses graphite, diamond and ice; the first two have been analysed successfully, but the last has not.

How do these calculations proceed, and what is the state of the art? Maddox focuses on a study<sup>5</sup> of polymorphs of silica, an interesting calculation which requires input information about  $\text{SiO}_4^{4-}$  clusters. Maddox describes the achievements of the calculations and mentions some reservations about them. He notes the need to add fictitious positive charges and to set the distances between oxygen atoms and the point charges equal to the observed Si-O distance, for example, observing that it is wrong to say that "everything depends on what the programmers have done". Most researchers in this area would agree with this observation, but there are approaches which do not call for caveats of this kind.

The present state of this area can be assessed by a more detailed examination of the silicon calculation<sup>2</sup>. The procedure is to compute the total energy by summing the interactions between and among the cores and valence electrons. The core-core repulsion is computed with standard techniques for evaluating the Coulomb electrostatic energy between fixed cores using Madelung sums (the sum of Coulomb repulsions over a whole lattice). The electron-electron contribution to the energy can be estimated directly from the electron density as a function of position in the crystal. The electron-core term is more difficult because the interaction between a valence electron and a core has two main components: the attractive Coulomb interaction and the repulsion arising from the Pauli exclusion principle. Both of these can be incorporated into a pseudopotential which can be constructed for all the atoms in the periodic table and beyond. These potentials are particularly suited to the description of electrons with low angular momenta, but that is not a severe limitation. In principle, solids with many atoms in a unit cell can be studied.

### Refined approaches

The progress in this area is well-documented in the literature (see, for example refs 6,7) and many researchers are contributing to the refinement and improvement of these approaches. There is particular interest in the development of schemes to treat excited electron states, to improve the precision of calculating static properties such as cohesive energy and to avoid the need of starting with a list of candidate structures.

There has been significant progress in all three areas. It is now possible to use the first-principles approach to compute optical and photoemission properties of

solids without any experimental input. When electrons are excited by light or heat they interact differently with the other electrons in the solid. Several computations of these changes have been done based on new theoretical approaches<sup>8</sup> and fairly complex calculational techniques. The refinements in the evaluation of electron-electron interactions beyond schemes which use only the position-dependent density of the electrons are mostly based on extensions of a statistical approach to the encounters between a finite number of electrons. These quantum Monte Carlo simulations<sup>9</sup> provide the data needed to treat the electron-electron interactions more exactly.

Finally, statistical approaches<sup>10</sup> may allow the determination of crystal structures without tests of candidate structures. By allowing cores to move randomly and in a manner so as to minimize the energy of the entire system, including contributions from the sea of valence electrons, it is expected that the lowest energy structure at a given volume will be the same as nature's choice for that volume. There are problems with this approach, which arise because systems tend to choose local energy minima that are configurations of low energy with core positions close to the starting configuration. These may not be the lowest or global energy minimum, and the solids they predict may be unattainable metastable states of the system. Nevertheless, this problem should be overcome before too long.

In general, the outlook is bright for the development of theoretical approaches with the predictive power envisaged by Maddox. In addition to enabling us to simulate extreme conditions for making materials, with theoretical models we can easily vary the constituent elements in a compound. Unlike experiment, where each change of an element usually requires starting the synthesis all over again, theoretical modelling requires small adjustments and new combinations are tested quickly. The search for new materials using theory can be made more efficient and faster if partially empirical approaches are used. For example, a calculation of the bulk modulus ( $B$ ) or its inverse, compressibility, for a class of tetrahedral semiconductors requires significant computer time when the first-principles theory is used. But a simpler scaling theory<sup>11</sup> gives the results with comparable accuracy using a hand calculator. The formula is

$$B = (1.971 - 220\lambda)d^{-3.5}$$

By inputting  $d$ , the bond length in Ångströms, and the ionicity parameter  $\lambda = 0, 1, 2$  for Group IV, III-V or II-VI semiconductors, respectively, the bulk modulus  $B$  in gigapascals is obtained with remarkable accuracy<sup>11</sup>. The full theory was used to provide the basis and the tests of this simpler approach, but now the

formula for  $B$  can be used to give insight into materials development.

### Hard as diamond

An example of the use of the formula for  $B$  is in the search for materials with hardness comparable with that of diamond. Hardness is generally directly related to the bulk modulus, and diamond has the largest bulk modulus of all materials. It is a tetrahedral material with a very short bond length ( $d$ ) and zero ionicity ( $\lambda = 0$ ). However, it should be possible to create materials with bulk moduli comparable to or even larger than that of diamond by reducing the bond length. One approach<sup>11</sup> is to attempt a synthesis of tetrahedrally coordinated insulators using carbon and nitrogen because the C-N bond length could be shorter than that of diamond. Even though a material of this kind will be partially ionic, the shorter bond length can over-compensate and increase  $B$ . Boron nitride is another superhard material of interest. The results for  $B$  using the above formula and a complete first-principles theory predicting  $B$  and the equation of state for boron nitride were tested<sup>12</sup> recently by direct experimental measurement. The predictions were found to be in excellent agreement with experiment.

Although the development of less-complex empirical approaches is likely to have a great influence on the development of useful materials, the emphasis at present is on the application and refinement of the first-principles theory. Research on the possibility of compressing hydrogen into a metallic state, the possibility of high-temperature superconductivity for metallic hydrogen, the existence of superhard systems and the general search for useful new materials can be aided by first-principles theory. Some materials have already been identified in this way and it is likely that more will be found as a result of theoretical predictions. □

# Soap bubbles make serious physics

A new study of the evolution of rafts of soap bubbles confirms expectations and earlier measurements, but has the distinction of having been carried out with a photocopying machine.

Using a Xerox or some other brand of photocopying machine, with virtually no extra equipment, to make interesting physical observations is an achievement in itself. But Joel Stavans from the University of Pittsburgh and James A. Glazier of the University of Chicago seem also to have won some interesting physics from their primitive equipment (*Phys. Rev. Lett.* **62**, 1318; 1989). The issue is the evolution in time, by coalescence and other means, of a raft of soap bubbles which are small to begin with, but which get larger with the passage of time.

As with so many other topics, that of the evolution of a bubble raft goes back at least to J. von Neumann, among other things the author of a law describing the evolution of a single bubble embedded in a raft of them. It is important that, in circumstances such as these, bubbles are not circular or spherical but, rather, sit like prisms on polygonal bases. The neat way of fixing ideas is to imagine the experiment which Stavans and Glazier describe: put a raft of coloured soap bubbles in a very shallow plastic tray and seal a lid on top in such a way that the soap films stretch between the flat and horizontal upper and lower surfaces, giving each bubble (to a first approximation) the same height. Liquid collects at the lower boundaries between contiguous bubbles, so that the evolution of the bubbles in a raft may be followed simply by pressing the button on the photocopier at convenient intervals.

A bubble will grow or shrink by the diffusion of supporting gas from all nearest neighbours, which leads directly to von Neumann's law of bubble-growth that the rate of change of the volume of a bubble (or of its area as seen in a photocopied image) depends only on the number of vertical faces it presents to its neighbours in the raft, or on the number of sides of the polygon which forms the base. The starting-point for the argument is that a strictly regular array of bubbles each of which is hexagonal should be indefinitely stable, which leads directly to the rule  $da/dt = \kappa(n - 6)$ , where  $a$  is the projected area of the bubble,  $n$  the number of sides and  $\kappa$  a kind of diffusion constant.

The simplicity of this result is geometrical, deriving from the way in which both that rate of inward diffusion and the volume of the prism is determined by the total area of the vertical faces of the prismatic bubbles. A further assumption

is that the internal angles of each polygonal bubble-base are exactly  $120^\circ$ , which seems reasonable enough, given that each vertex of the polygon is a point at which three prismatic bubbles join: to a first approximation, they may be assumed to join symmetrically. But naturally this can be exactly true only when all bubble bases are regular hexagons. Otherwise, the sides of the polygonal bases will not be straight lines, but curves.

Stavans and Glazier are not primarily concerned with single bubbles, but with rafts of them, for which purpose they work with a distribution function called  $\varrho(n)$  which gives the frequency in any sample of the evolving bubble raft of bubbles with  $n$  sides, where  $n$  is necessarily an integer running from 3 to infinity.

Simple observation is said to show that the first stages of the evolution of the raft are rapid, with larger bubbles growing at the expense of smaller neighbours and the sidedness of particular bubbles changing upwards and downwards both by the disappearance of smaller neighbours and by a process in which vertical membranes shift so as to trade sides between one bubble and a neighbour. (Those planning to use their office photocopier for further investigations along these lines should beware of the edge effects, which complicate both the statistics and the underlying phenomenon.)

The authors explain how, when they made soap bubbles with helium gas, the general appearance of the raft thus formed was that of several patches of regular hexagonal bubbles interspersed with regions in which five and seven-sided polygons were mixed together. But the striking result, confirming earlier conjectures, is that there comes a point in the evolution of a bubble-raft in which the distribution function  $\varrho(n)$  becomes essentially invariant in the course of time. Moreover, the mean of the distribution (that is the average number of sides per bubble) is almost but not quite six, whatever the length of time for which the raft has been evolving (in one run, indeed, measurements extended over a day and a half). Only when the total number of bubbles becomes very small does the distribution go awry.

The same point emerges from measurements of the second moment of the distribution (essentially the weighted average of the squared deviation of the number of sides per cell from the average

value). Again, in at least two different systems, the value of the second moment fluctuated widely to begin with, but then quickly settled down to what seems to have been a constant value (estimated at  $1.4 \pm 0.4$ ). The interest seems to be that, as in fractal and chaotic systems, there seems to be an underlying scaling law which describes how, in an ageing raft of bubbles, the bubbles all get bigger, but the statistical properties of the quantity appropriately called sidedness remain essentially constant.

Departures from the rule that the internal angles of the basal polygons of each bubble should be  $120^\circ$  excite particular interest. What the measurements show is that bubbles with fewer than six sides have internal angles smaller or equal to  $120^\circ$ , but that bubbles with more sides have larger angles (although  $130^\circ$  seems to be the limit). Stavans and Glazier argue that the presence of angles differing from the expected value implies the accumulation of strain energy in the system, which allows them to generalize von Neumann's law (but only for those systems in which all the bubbles have the same number of sides) to take account of these departures from the expected. One practical conclusion seems to be that it is possible to understand why one bubble may grow at the expense of a neighbour with the same number of sides.

There remains one puzzle. Perhaps the simplest measure of the state of an ageing bubble raft is the average bubble area, which should, by simple integration of von Neumann's rule, be proportional to the time elapsed. But neither Stavans and Glazier nor their predecessors in the field have been able to measure anything like that — they quote a figure of  $0.59 \pm 0.11$ , as the exponent in a simple power-law dependence on the time.

Why should such a simple prediction apparently be so wide of the mark? It is natural that people should have gone haring after fanciful explanations to do with the scaling laws as bubble-rafts age. Prosaically, the authors suggest a more mundane explanation — that as a raft ages, more soap solution accumulates beneath the raft while there are thicker layers of it between membranes, the effect of which is to reduce the diffusion constant between neighbouring bubbles. It all goes to show that there are merits in even the least reliable photocopies.

John Maddox

# Dissecting a molecular motor

Peter Hollenbeck

THE organelles undergoing directed transport within eukaryotic cells are a strikingly diverse group. They vary widely in function and composition — consider membrane vesicles, pigment granules, mitochondria, and nuclei, for example — and range over at least two orders of magnitude both in their size and in their velocity of movement. Given this variation in the cargo, it is no surprise that cells use several different mechanochemical systems to generate force for movement. Two of these are well-characterized: myosin ATPase, which drives movement along actin filaments; and dynein ATPase, which generates unidirectional movement towards the 'plus' ends of microtubules. A third, kinesin, has not yet been so well characterized. On page 355 of this issue<sup>1</sup>, Scholey *et al.* describe the coordinated use of protein biochemistry, molecular genetics, antibody probes and electron microscopy to analyse the properties of kinesin, which should allow a comparison of these mechanochemical enzymes.

Although they interact with different filament systems, and have different kinetic properties, myosin and dynein have some interesting similarities<sup>2</sup>. In addition to a common structural motif (see figure), they share a crossbridging mode of force generation; they bind to the structure to be moved, thus crosslinking it to a filament; and hydrolyse ATP, transducing the energy thus liberated into movement along the filament. Several groups have dissected the kinesin molecule in attempts to fit its mode of action into this scheme, and Scholey *et al.*<sup>1</sup> are now able to assign the various activities of the kinesin molecule to different structural domains. They find that kinesin has an architecture very similar to myosin and dynein.

Kinesin, whose discovery and characterization I have discussed previously in News and Views<sup>3,4</sup>, is a ubiquitous protein motor which generates movement along microtubules in the opposite direction to dynein, and is believed to be involved in anterograde (or centrifugal) organelle transport. It is a heterotetramer, each molecule consisting of two ATP-binding heavy chains of relative molecular mass 110,000–140,000 (110–140K) and two 60–65K light chains<sup>5,7</sup>.

It appears in the electron microscope to have two globular heads at one end of a narrow stalk, similar to dynein and myosin, as well as a smaller pronged or fan-shaped region at the other end of the stalk<sup>8</sup>.

Degradation of the heavy chain with proteolytic enzymes yields a resistant 45K

The studies by Scholey and collaborators reported in this issue<sup>1</sup>, as well as recent work by Hirokawa *et al.* reported in the current issue of *Cell*<sup>11</sup>, combine several experimental approaches to map the location of specific functional domains on the kinesin molecule. Scholey *et al.* use freeze-etch electron microscopy of kinesin to show that an antibody which binds the 45K heavy-chain fragment and inhibits kinesin motility 'decorates' only the paired globular heads of the kinesin molecule. In addition, they use a series of

truncated kinesin heavy chains (produced by transcribing and translating truncated complementary DNA encoding the heavy chain) to demonstrate that the 45K fragment represents the amino-terminal one-third of the molecule, and that the inhibitory antibody binds near the carboxy-terminal end of the fragment, where the globular and  $\alpha$ -helical regions of the heavy chain meet. In a related study, Yang *et al.*<sup>12</sup> confirm that the amino-terminal portion of the heavy chain is necessary for microtubule binding.

Using quantitative morphometry of rotary-shadowed kinesin, Hirokawa *et al.*<sup>11</sup> show that monoclonal antibodies specific for the kinesin heavy chain decorate only the globular head regions, whereas those specific for the light chain decorate the fan-shaped region of the molecule at the opposite end of the stalk. These authors also report ultrastructural evidence that the globular heads interact with microtubules, whereas the feathered region, and perhaps a portion of the stalk, interacts with the moving structure.

A coherent picture of kinesin is emerging from these studies: the amino-terminal region of the heavy chains, residing in the globular heads, contains the microtubule-binding and ATP-hydrolysing capacities of the molecule; a flexible stalk connects this business end to an organelle-binding domain; and a domain important for the coupling of ATP

Electron microscope images of 'motor' molecules prepared by adsorption to mica, freeze-drying, and replication with platinum according to Heuser<sup>14</sup>. *a*, Two 3-headed ciliary dynein molecules prepared from *Tetrahymena* by U. Goodenough; *b*, two 2-headed cytoplasmic dynein molecules prepared from chick cells by E. Steuer; *c*, four myosin molecules from *Acanthamoeba*, one of which is attached to an anti-tail monoclonal IgM molecule (the asterisk-shaped entity in the lower left) (D. Kiehart); *d*, four kinesin molecules prepared from chick brain tissue by T. Schroer. Bar, 40 nm. (Courtesy of John Heuser.)

fragment which provides an important key to kinesin's fine structure. Kuznetsov *et al.*<sup>9</sup> analysed this fragment in detail and determined that kinesin's ATP hydrolysing and microtubule-binding activities reside there; in fact, the fragment shows elevated levels of both activities relative to the intact molecule. It is significant, however, that the fragment is not capable of generating movement in an *in vitro* assay. Ingold *et al.*<sup>10</sup> demonstrated that the fragment contains the binding sites for several monoclonal antibodies which inhibit kinesin-driven movement *in vitro* without inhibiting kinesin's microtubule-activated ATPase activity. This suggests that the fragment contains at least two functional domains — the ATPase site and an additional region distinct from the ATPase site but nonetheless essential for force generation.

hydrolysis to force generation lies near the junction of the globular head and the stalk. The complementary DNA sequence of the heavy chain, determined by Yang *et al.*<sup>12</sup>, provides additional support for this picture; it predicts a large amino-terminal globular region containing an ATP-binding sequence, connected to a small carboxy-terminal globular region by a long stretch capable of forming an  $\alpha$ -helical coiled-coil<sup>12</sup>. This sequence also shows a proline-glycine break at approximately the region where a kink appears in electron micrographs of the stalk<sup>8,11</sup>.

So far, so good — but studies in which

organelle movements have been reconstituted *in vitro* from cell fractions suggest that a further functional domain of kinesin awaits identification. Schroer *et al.*<sup>13</sup> have shown pure kinesin alone is not enough to produce movement of salt-stripped membrane vesicles; additional factors are required. The sites of interaction between these potential regulatory factors and the kinesin molecule remain to be found. □

## SUPERNOVA 1987A

# The remnant's rapid heartbeat

M. A. Alpar, I. Fushiki, F. K. Lamb, G. S. Miller, M.-G. Park and D. Pines

THE supernova explosion of February 1987 in the Large Magellanic Cloud has so far provided a wealth of data which, at least in broad outline, has confirmed our expectations of such an event and its aftermath. As the diffuse remnant has expanded and faded, astrophysicists have watched with mounting anticipation for any indication of the pulsar expected to have been formed in the explosion. The report by Kristian *et al.* in last week's issue<sup>1</sup> of optical pulses with a period of 0.5 ms is the first indication of such a pulsar. This report has aroused enormous interest among astrophysicists, as illustrated by the papers by Woosley and Chevalier<sup>2</sup> and Wang *et al.*<sup>3</sup> on pages 321 and 319 of this issue. It challenges almost all the main features of current theories of neutron-star formation, structure and evolution, and, most fundamentally, current models of nuclear interactions and the equation of state of matter at the highest densities. It seems to us that there are three possible interpretations of these results.

The most interesting possibility is that the pulses are produced by a neutron star rotating with a period of 0.5 ms, three times faster than any previously discovered. If so, this would strongly challenge the picture that has emerged from 20 years of research on neutron-star structure and the equation of state of dense matter. The near consensus has been that pulsars such as the Crab and Vela pulsars are spinning neutron stars of about 1.4 solar masses ( $M_{\odot}$ ) and with radii of 10–15 km. This reflects an equation of state describing neutron matter that is moderately stiff.

Models of pulsar glitches and post-glitch relaxation, the interpretation of the 35-day cycle of Her X-1 as neutron-star precession and deductions of the nuclear interactions from heavy-ion collisions<sup>4</sup>, all suggest that the equation of state of dense matter is relatively stiff. The only uniformly rotating models that predict neutron stars that are sufficiently compact

not to fall apart with a 0.5-ms rotation period are based on soft equations of state: the simultaneous demands that the equation of state be stiff enough for slowly rotating neutron stars with gravitational masses as high as  $1.4 M_{\odot}$  to exist and soft enough to permit the existence of a neutron star with a 0.5 ms rotational period are very constraining. The evidence for a stiff equation of state might be reconciled with a rotational interpretation of the reported pulsar if it had a very high central density, and if matter undergoes a phase transition at such high densities. This would then leave the question: why should SN1987A have left a particularly dense remnant?

The 0.5-ms rotation period would also constrain the dipole magnetic field strength  $B$  at the neutron-star surface. Electromagnetic dipole radiation has a power output proportional to  $B^2\omega^4$ , where  $\omega$  is the rotation rate. For this power to be less than the  $10^{36}$  ergs  $s^{-1}$  current total luminosity of the supernova remnant, the surface dipole field must be less than about  $10^9$  gauss (G). The magnetic fields of all of the relatively young (but not newborn) pulsars, of which the 1,000-year-old Crab pulsar is the paradigm, are estimated to be  $10^{11}$ – $10^{13}$  G. The pulsar implied by the report of Kristian *et al.*<sup>1</sup> would resemble these familiar objects only if the magnetic field can increase by a factor of about  $10^3$  within a thousand years — a possibility that was suggested some years ago, but which is highly speculative.

The alternative assignment of such a weakly magnetic pulsar to the class of other millisecond pulsars which have typical field strengths  $10^8$ – $10^9$  G challenges the widely accepted view that such pulsars are formed in low-mass binary systems (see the discussion by F. Graham-Smith<sup>5</sup> in News and Views last year). It is thought that such pulsars previously had periods of the order of seconds, and that their strong primordial fields have decayed. The combination of a weak magnetic field and

a high rate of accretion from the partner object in such binaries allows the neutron star to be spun up to a millisecond period. The periods, magnetic fields and ages of millisecond pulsars and rotation-powered pulsars in binary systems are consistent with this model. The location of some millisecond and binary pulsars in globular clusters, and the view that the fast quasi-periods observed in the low-mass X-ray binaries result from  $10^9$ -G magnetic fields in neutron stars rotating with millisecond periods, also fit this model.

It is conceivable that the weak magnetic fields in these seemingly old systems are primordial and do not result from the decay of stronger initial fields. Subsequent rapid accretion would then leave the star rotating with a millisecond period. But if the newly identified object in SN1987A is a newborn pulsar with both a weak magnetic field and a short spin period, this would undermine the model of spin up by accretion.

Woosley and Chevalier in this issue<sup>2</sup> propose that the pulsar was spun up to its millisecond period in the hours immediately following the supernova explosion. For this to occur, the neutron star's magnetic field must act to transfer angular momentum from the supernova envelope to the neutron star in a way similar to that supposed in the model for accretion from a binary partner. This explains, the authors suggest, why the new pulsar has the same field-period correlation as the other millisecond pulsars. But the high accretion rate necessary in this model means that the mechanism for generating the observed pulses must be different from that in canonical pulsars. Also, one might expect the accreting material to smear the pulses by scattering.

If the 0.5-ms period is established to be a rotational period and this pulsar turns out to be in the same class as the previously known millisecond pulsars, a fundamental revision of our ideas of pulsar classes, statistics and evolution will be required. Given a neutron star with such an unusual structure and spin period, the natural question for astronomers will be whether the progenitor star and the supernova event itself were peculiar. Do such blue giants have unusually weak magnetic fields, rapid rotation rates or peculiar internal structures? Even if systematic differences are identified, supernova theorists will face the challenge of linking them to distinct features of the stellar core that collapses to become the neutron star.

An alternative possibility proposed by Wang *et al.* in this issue<sup>3</sup> is that the neutron star is ringing, or vibrating, with a period of 0.5 ms. A particular attraction of this idea is that it does not require a new and different kind of object or a radical revision of our current understanding of neutron stars and pulsars. Indeed, a 0.5-ms radial vibration would be typical of neutron stars

with reasonable masses and equations of state. Historically, neutron-star vibrations were rejected as an explanation of pulsars because vibration periods are much shorter than the vast majority of observed pulsar periods, and because the observed pulses must persist for thousands to millions of years. Such persistence is natural for neutron-star rotation, but difficult for vibrational oscillations, which are expected to be damped within a few hundred years. However, this need not pose a problem for a newborn pulsar, because radial modes excited at the time of formation may not yet have been damped.

Wang *et al.* propose that some of the vibrational energy is converted into the observed light pulses by the formation of a shock front as the vibrations propagate into a thin surface region of the star where the density and sound speed decrease very sharply. The model requires the shock to accelerate iron ions to energies of 100 GeV; the ions subsequently emit cyclotron radiation without losing much of their energy to electrons or lighter nuclei. A surface magnetic field of  $10^{12}$  G is needed for the iron ions to emit radiation in the optical band. Light nuclei and electrons would be relativistic at 100 GeV, and hence would require lower magnetic fields to emit predominantly in the optical; their synchrotron lifetimes would then be longer than the observed pulse period, washing out the pulsations. Wang *et al.* postulate that the field is  $10^{12}$  G, in which case the rotation period must be longer than 0.1 s or the dipole radiation power would be more than the current supernova luminosity. Stable polarized pulses indicating rotation with a period in this range would provide strong support for the radial-oscillation hypothesis.

Confirmation of the vibrational mechanism, which would not challenge the existing theory, would focus new attention on aspects of neutron stars such as the structure of their surface layers, the propagation of radial oscillations and shocks, and the coupling of such motions to rotation, non-radial modes and possibly to gravitational radiation. There would also be renewed interest in the generation of optical pulses, either through the mechanism proposed by Wang *et al.* or by other means. Nevertheless, it is hard to see why the harmonic content of the observed pulses should closely match that of the Crab pulsar, if the pulsation mechanism is indeed so different. In particular, if the pulse has two peaks, a main pulse and an interpulse, as is suggested by the relative strengths of the fundamental and first harmonics, then this may be difficult to model with vibrationally driven pulsations.

Whatever the explanation for the pulses, there seems also to be an 8-hour sinusoidal modulation of the pulse period,

which poses additional problems. Precession of the neutron star cannot account for the large phase offset observed. Proposals that the modulation is the result of timing noise must confront the comparatively noiseless sine curve of the observed data: it is possible, but unlikely, that this has been produced by a random process. The idea that the modulation arises from a Doppler shift as the pulsar orbits a small, unseen companion, raises the problem of explaining how a companion comes to be so close to the neutron star. It is very unlikely that material left over from the progenitor star would be able to cool and condense into a gravitationally bound companion. Had the companion existed independently before the explosion, it should have had to exist within the progenitor star. But perhaps a companion was produced as the result of spin-up of the core during the supernova implosion.

The third possibility, and the least appealing one, is that the observations are

not what they seem, and that no pulsar has actually been detected, despite the strong signal observed and careful analysis. This would save us the trouble of revising our cherished beliefs, but would leave us wondering uncomfortably what was observed, if not a pulsar? Still, until the report of Kristian *et al.* is confirmed by further observations, this is a possibility that must be considered. Should the report not be confirmed, the questions which it has raised may well remain unresolved. This would surely be a disappointment, in view of the exciting challenges the initial report has posed. □

## METEORITES

# Unique find from Antarctica

Robert T. Dodd

METEORITES, it is generally agreed, are mostly pieces of pre-planetary material that both come from and were formed in asteroidal parent bodies. This interpretation makes meteorites uniquely important as witnesses to events in the primitive solar nebula, but it also raises a serious question about how typical they are of nebular material. Well-classified meteorites come from no more than 20 of the thousands of asteroids that have been described. Worse, spectral reflectance comparisons suggest that the most abundant meteorites — ordinary, or common, chondrites — come from very rare asteroids: the dark objects that are most numerous in the asteroid belt have, in contrast, yielded few meteorites. So it seems that our sample is incomplete and strongly biased towards those asteroids that are now well-placed to deliver meteorites. If so, meteorites recovered from the Antarctic ice cap, some of which fell a million or more years ago, may both introduce us to new kinds of meteorites and provide fresh insights on old problems. Allan Hills 85085, a thumb-sized Antarctic meteorite described recently in three consecutive papers in *Earth and Planetary Science Letters*<sup>1–3</sup>, does both.

Despite suggestions to the contrary<sup>4</sup>, ALH85085 seems to be a chondrite: it contains both the spherical-to-rounded objects — chondrules — from

which such meteorites take their name and inclusions of highly refractory calcium–aluminium silicates (CAI) like those found in many carbonaceous chondrites. It is, however, sufficiently different from other chondrites to make its classification difficult. Its chondrules are few, small, and accompanied by much fragmental material. According to Scott<sup>1</sup> and Weisberg *et al.*<sup>2</sup>, its silicate particles are very closely sized, and the associated oblong metal particles appear to have a preferred orientation<sup>2</sup>.

ALH85085 lacks the extremely fine-grained, dark matrix material that surrounds chondrules in other primitive chondrites, but it contains lumps of similar material which at least resemble<sup>1,2</sup> and, according to Grossman *et al.*<sup>3</sup>, may in fact

Metal–silicate fractionation trends in chondrites. Mean ratios have been normalized to the Si/Mg ratio in CI chondrites to remove the effect of refractory element fractionation. Data from refs 3 (ALH85085) and 7 (chondrite groups). ■, C groups; ×, E groups; □, O groups; ☒, ALH85085.

## CORTICAL PHYSIOLOGY

## Is grandmother an oscillation?

Michael P. Stryker

be fragments of chondrule-poor carbonaceous chondrites. The meteorite also differs from other chondrites in chemical composition<sup>1,2</sup>: it is enriched in iron, nickel and other siderophile elements and is deficient in sulphur, alkalis and other elements that vaporize at low temperatures (volatiles).

Those who have studied ALH85085 agree that it is a unique meteorite, whose composition and mineralogy suggest that it is most closely related to two unusual carbonaceous chondrites, Renazzo and Al Rais. Whether it should be grouped with those meteorites<sup>3</sup> or left unclassified<sup>1,2</sup> is less certain. An oxygen isotope analysis or a cosmic-ray exposure age, neither of which is now available, may answer that question.

Of the many intriguing features of ALH85085, its enrichment in siderophile elements and depletion in volatile elements are most significant, for they seem to answer a long-standing question. Almost two decades ago, Larimer and Anders proposed<sup>4</sup> that other kinds of chondrites evolved from material similar to the chondrule-free CI carbonaceous chondrites (*sic*) by extraction of metallic nickel-iron and refractory calc-aluminous silicates.

Their interpretation, perhaps modified to allow for two episodes of metal fractionation<sup>5</sup> (see figure), is plausible and widely accepted, but it leaves a great deal of siderophile material unaccounted for. Hence the discovery of a chondrite that contains excess metal of about the right composition<sup>2</sup> is important, both for the chemical evolution of chondrites and for the origin of other objects — the Earth and Moon included — that also appear to have formed from atypical chondritic material<sup>1</sup>.

To date, most meteorites from Antarctica have turned out to be samples of known types or modest variations on familiar themes. If the Earth receives a biased sample of the meteorite sources, it seems that it has done so for at least a million years. Yet the ice cap has already yielded many unusual and important objects, which include the first lunar meteorites and additions to a small collection of meteorites from Mars. ALH85085 shows that even its smallest gifts may open new windows on the origin of the Solar System. □

Robert T. Dodd is in the Department of Earth and Space Sciences, State University of New York at Stony Brook, New York 11794, USA.

THE realization that visual information is processed through successive stages in many separate areas of the cortex has led to a dilemma. How are the distributed representations of the visual features that have to do with a single object in the world put together so that they can create a perception or influence action? That is, when a green furry tennis ball and an ebony billiard ball are seen in the same part of the visual field, how can the colour, motion and texture properties of each ball be associated, so that the black colour and smooth texture of the billiard ball is not ascribed to the tennis ball? Three new papers<sup>1-3</sup> from two laboratories, one on page 334 of this issue<sup>2</sup>, provide a clue.

Several proposals have been put forward to solve this problem. A now-classic notion is that significant combinations of features are hierarchically extracted and combined in specific cortical areas specialized for the recognition of certain classes of objects<sup>4,5</sup> or, at the extreme, in the receptive fields of single neurons<sup>6</sup>. In some higher cortical areas, there could be, for example, 'grandmother' neurons responding selectively to the precise combinations of visual features that are associated with one's grandmother. Either such cells would not be able to signal the location of stimuli very accurately or there would have to be a separate grandmother cell for each region of the visual field. It is also not clear how the many different features that might be associated with one's grandmother could be combined in any very selective way without a 'combinatorial explosion' in the numbers of cells required<sup>7</sup>. This would lead to the sort of problem Little Red Riding Hood had when her grandmother cells failed to discriminate the wolf's grey fur, sharp white teeth and heavy breathing from her grandmother's normal benign appearance.

These shortcomings have led to an alternative notion — that the representations in the brain of various visual properties of objects in the world are combined only transiently, rather than in fixed receptive fields, in some way that makes the conjoint output of different property-specific detectors available to the mechanisms for perception or action. Some years ago, Crick<sup>8</sup> suggested a mechanism by which the neurons of thalamic reticular nucleus below the cortex could unify the perceptual qualities represented in different cortical areas. He proposed that a neural 'searchlight' would simultaneously illuminate all the neurons that are activated by the same object in the world.

The recent work from Gray, Singer and colleagues, reported in this issue<sup>2</sup> and else-

where<sup>1</sup>, and from Eckhorn and colleagues<sup>3</sup>, raises a related possibility: that neurons in the visual cortex activated by the same object in the world tend to discharge rhythmically and in unison. Such a one-note neural harmony could, in principle at least, provide the neurons at higher cortical levels with stronger inputs so that they associate the activities of lower-order neurons with one another (see figure). If the discharges of the texture-, colour-, depth- and movement-sensitive neurons

Four lower-order neurons providing input to one higher-order neuron. *a*, Neuronal activity in the lower-order neurons is shown oscillating in phase. The resulting postsynaptic potentials sum in the target cell, producing a large oscillation in its membrane potential. At the peak of this oscillation, the membrane potential of the higher-order neuron would exceed the discharge threshold, and the cell would fire rhythmic, high-frequency bursts of spikes. *b*, The activities in the lower-order neurons do not oscillate in phase, so the higher-order neuron receives a more nearly constant input. The resulting steady membrane potential in the higher-order neuron either would be below the threshold for spike discharge or would, in any case, not allow it to discharge at the high frequencies characteristic of neuronal responses to sensory stimuli.

concerned with the tennis ball were to oscillate in phase with one another and out of phase with the billiard ball responses, this might enable perceptual mechanisms to assign the furry texture, green colour and blinding speed to the one object and the smooth texture, ebony colour and moderate speed to the other. I have made a simple estimate that, with reasonable assumptions about the duration of postsynaptic potentials, such a mechanism would enable higher-order cells to distinguish inputs from one set of neurons from those of 10 or more sets of neurons, if each set responds to different objects in the world at different phases or frequencies. If, instead of summing, synaptic inputs can interact multiplicatively<sup>9</sup>, cortical cells could detect phase-locked activity with even more sensitivity.

This new evidence provides only the first hints that the visual cortex uses such mechanisms. Gray and Singer<sup>1</sup> find that visual stimulation can cause many neurons in visual cortex to discharge their action

potentials rhythmically at about 40–50 Hz in very lightly anaesthetized (and, as reported in an abstract elsewhere, awake) animals. This rhythmicity is accompanied by an oscillation in the extracellular field potential and seems to originate in the cortex, as it was not evident in recordings from the main input to the visual cortex from the thalamus. Eckhorn and colleagues<sup>1</sup> find that oscillatory field potentials evoked by some visual stimuli are in phase even between the two primary visual cortical areas (17 and 18) in the cat and that the field potentials in one area are in phase with the action potential discharges in the other. In their paper in this issue<sup>2</sup>, Gray *et al.* report that oscillations in the discharge are commonly in phase for neurons with overlapping receptive fields, irrespective of their selectivity for a particular stimulus orientation<sup>3</sup>. But when the authors record at sites more than 2 mm apart, where receptive fields no longer overlap, they find that oscillations are rarely in phase except for neurons with the same orientation specificity.

The most surprising observation comes from two cases in which pairs of recording sites were located half a visual cortex (7 mm) apart. Receptive fields of the neurons at the two sites had a common orientation specificity and were aligned so that they could be stimulated by a single long bar of light (see Fig. 3b of ref. 2 on page 336). Neuronal discharges at the two sites were well correlated only when the cells were stimulated with a single long bar. When they were simultaneously activated by two shorter bars that did not bridge the gap between the two receptive fields, the correlation disappeared. In that sense, the correlated discharge can be considered as depending on the global property of the stimulus — whether it is a single or two different objects.

Numerous questions are raised by these tantalizing observations. Where does the rhythm come from? Many workers have dismissed findings of rhythmic discharge in the central nervous system as artefactual, as rhythmicity can be induced by certain anaesthetics or by damage. Further work demonstrating that such phenomena are definitely present in awake animals will be needed to satisfy these critics. Even if not an artefact, the oscillations may be epiphenomena:

observations of rhythmicity and its correlation with particular stimuli do not allow the conclusion that the nervous system makes use of such information. This point will be difficult to address except by demonstrating that many global aspects of visual stimuli are accompanied by correlated rhythmic discharges. In particular, it would be intriguing to know whether a single bar or edge produces such correlated activity when and only when it appears as a single object; a physical discontinuity that does not degrade the perception of the bar as a single object, as when the bar is partially occluded<sup>4</sup>, should not destroy the correlated oscillations. It will be even more intriguing to see whether neurons in the different cortical areas specialized for colour, depth, motion and so on exhibit correlated, rhythmic discharges when

## PRIONS

# Sheep disease in human clothing

Charles Weissmann

THE identification of polymorphic markers linked to a genetic disease is an important goal both for geneticists and for molecular biologists. The former make use of the association to determine individuals at risk for the disease, the latter to hunt for the gene causing it. Because it is based on trial and error, the search is often protracted. But this is not the case in the familial (ataxic) form of Gerstmann-Sträussler syndrome, a transmissible neurodegenerative disease so rare that it is not mentioned in the human geneticist's bible, *Mendelian Inheritance in Man*<sup>1</sup>. Guided by their work on scrapie, a related brain disease of sheep, Prusiner and colleagues, as they report on page 342 of this issue<sup>2</sup>, have in one fell swoop identified a polymorphic marker tightly linked to this syndrome. At the same time, these authors provide persuasive evidence that a surface membrane protein in neurons called PrP has a central role in the pathogenesis of the human disease.

Gerstmann-Sträussler syndrome and Creutzfeldt-Jacob syndrome in humans, as well as scrapie and bovine spongiform encephalopathy in animals, belong to a class of slow, transmissible, lethal brain diseases caused by an unusual kind of pathogen which Prusiner<sup>3</sup> called a prion. The main pathological features of prion-associated diseases are vacuolation of neurons, proliferation of glial cells and occurrence of amyloid plaques containing a form of PrP. The diseases have extended incubation times that can be greater than 30 years.

Scrapie has been used as a model for prion diseases because it has been transmitted to hamster and mouse, making it suitable for experimentation. Because scrapie infectivity is very resistant to heat

they respond to the same stimulus in the real world.

Observations of this type could provide compelling evidence that perceptual mechanisms of the brain do engage in the analysis of brain rhythms. The suggestion that coherent oscillations in activity identify the members of subsets of a large neuronal population may, however, still be an important one, even if these subsets are not closely tied to perception. Exploring the rhythms of the brain, revered by the pioneers of electroencephalography but now mostly dismissed as irrelevant to neural information processing, may even come back into fashion. □

Michael P. Stryker is in the Department of Physiology and the Neuroscience Graduate Program, University of California Medical School, San Francisco, California 94143, USA.

and nucleolytic agents but sensitive to procedures that modify or destroy proteins, it is unlikely to be caused by a conventional virus, plasmid or viroid. The unusual resistance of the infective agent to ultraviolet and ionizing radiation led not only to the conclusion that the mass of the agent is as low as 55,000 (55K) but also that it is devoid of nucleic acid altogether<sup>4</sup>.

Scrapie infectivity was purified several thousandfold from infected brain extracts by a procedure involving proteolysis under conditions where much of the protein but not infectivity is destroyed<sup>5</sup>. The resulting preparations contain a protein of relative molecular mass 27–30K, designated PrP 27–30, as the major component; although they are not free of nucleic acids<sup>6</sup>, no scrapie-specific polynucleotide has yet been identified in them, particularly no PrP-encoding sequence<sup>6</sup>. Surprisingly, PrP turned out to be a host-specified protein, encoded by a single exon of a unique host gene<sup>7</sup> and to be expressed both in normal and diseased animals<sup>8</sup>. Brains of scrapie-infected hamsters contain two forms of PrP: the scrapie (PrP<sup>Sc</sup>) and cellular (PrP<sup>C</sup>) isoforms. Both proteins have a mass of 33–35 K, but they have different physical properties. PrP<sup>C</sup> is anchored to the cell surface by a glycosyl phosphatidylinositol linkage<sup>9</sup> and can be solubilized with ionic detergents or phospholipase C, whereas PrP<sup>Sc</sup> cannot. PrP<sup>C</sup> disappears under proteolytic conditions while PrP<sup>Sc</sup> loses only an amino-terminal peptide to yield a protein of mass 27–30K called PrP 27–30. This is why PrP 27–30 is recovered from scrapie-infected but not from normal brains.

So far, no differences in the primary structure of PrP<sup>C</sup> and PrP<sup>Sc</sup> have been detected<sup>6, 8–10</sup>, nor have any differences

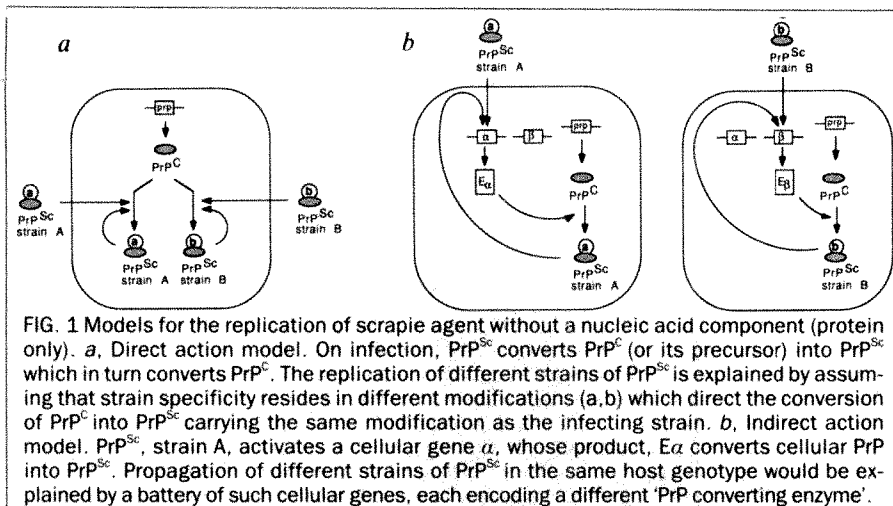

FIG. 1 Models for the replication of scrapie agent without a nucleic acid component (protein only). *a*, Direct action model. On infection,  $\text{PrP}^{\text{Sc}}$  converts  $\text{PrP}^{\text{C}}$  (or its precursor) into  $\text{PrP}^{\text{Sc}}$  which in turn converts  $\text{PrP}^{\text{C}}$ . The replication of different strains of  $\text{PrP}^{\text{Sc}}$  is explained by assuming that strain specificity resides in different modifications (a,b) which direct the conversion of  $\text{PrP}^{\text{C}}$  into  $\text{PrP}^{\text{Sc}}$  carrying the same modification as the infecting strain. *b*, Indirect action model.  $\text{PrP}^{\text{Sc}}$  strain A, activates a cellular gene  $\alpha$ , whose product,  $\text{E}\alpha$  converts cellular  $\text{PrP}^{\text{C}}$  into  $\text{PrP}^{\text{Sc}}$ . Propagation of different strains of  $\text{PrP}^{\text{Sc}}$  in the same host genotype would be explained by a battery of such cellular genes, each encoding a different 'PrP converting enzyme'.

been found between PrP genes or messenger RNAs from normal and infected brains with respect to structure or copy number. The physical differences between the two proteins are therefore attributed to a post-translational modification. It is known that PrP expressed in uninfected cells from the cloned PrP gene does not cause scrapie<sup>11</sup>.

Strains of scrapie prions differing with respect to incubation time and brain vacuolation pattern<sup>12,13</sup> can be passaged many times in the same inbred mouse strain and retain their characteristic properties. Interconversion of certain scrapie strains occurs reproducibly, particularly on transfer from one host to another<sup>15</sup>. Thus, scrapie prions have heritable properties. Incubation time is, however, also determined by a host gene designated *sinc* or *prn-i*<sup>12,14</sup>; remarkably, the *prn-i* gene is closely linked or perhaps identical with the PrP gene<sup>14,15</sup>. Mice with short and long incubation times have different amino acids in positions 108 and 189 of the PrP protein, suggesting that the structure of host PrP affects incubation time.

There are two main hypotheses for the

FIG. 2 Model for the replication of scrapie agent containing  $\text{PrP}^{\text{Sc}}$  and a nucleic acid. A nucleic acid associated with host-encoded  $\text{PrP}^{\text{C}}$  infects the cell. After replication of the nucleic acid, infectious particles are assembled from nucleic acid and PrP. Conversion of  $\text{PrP}^{\text{C}}$  to  $\text{PrP}^{\text{Sc}}$  is caused by the association with the nucleic acid, or (as here)  $\text{PrP}^{\text{C}}$  or its precursor may first be converted to  $\text{PrP}^{\text{Sc}}$ .

nature of the prion. First, the 'protein only' hypothesis proposes that the prion is a protein or protein derivative, devoid of nucleic acid<sup>3,4</sup>, for which  $\text{PrP}^{\text{Sc}}$  is the most likely candidate. The primary PrP translation product would have to be converted into the modified, infectious form in the  $\text{PrP}^{\text{Sc}}$ -infected cell. This conversion might be directly catalysed by  $\text{PrP}^{\text{Sc}}$  (ref. 16). Each scrapie strain would be represented by a different variant of  $\text{PrP}^{\text{Sc}}$  which modifies one precursor into a product resembling itself (Fig. 1a). Strain conversion on passaging in a different host could be accounted for by polymorphic variants of the resident PrP gene. In a more complex model, conversion of  $\text{PrP}^{\text{C}}$  to  $\text{PrP}^{\text{Sc}}$  would be catalysed by a host-encoded 'converting enzyme' induced by  $\text{PrP}^{\text{Sc}}$ . The variety of scrapie species would be explained by a battery of distinct converting enzymes, each activated by the cognate strain of  $\text{PrP}^{\text{Sc}}$  (Fig. 1b).

The second, 'nucleoprotein' hypothesis, postulates that the prion consists of a small nucleic acid and host-encoded protein<sup>3,17</sup> for which  $\text{PrP}^{\text{Sc}}$  is the most likely candidate (Fig. 2). Strain differences are ascribed to variations in the nucleic acid, just as in the case of viroid RNA.

How do the new data on Gerstmann-Sträussler syndrome reported in this issue<sup>2</sup> affect our knowledge of prion diseases? In two apparently unrelated families, one in the United States and one in the United Kingdom, Prusiner and colleagues find that an ataxic form of the syndrome is linked to a change in codon 102 in one of the PrP alleles from proline to leucine. Prusiner and colleagues do not find this mutation in 100 normal individuals or in 15 individuals suffering from other forms of inherited or sporadic prion diseases. Using the data from both pedigrees, assuming dominant inheritance and making certain assumptions regarding age-dependent penetrance as well as disease and marker frequencies, the authors calculated a lod score of about 3.3, which is highly significant evidence for linkage. As Gerstmann-Sträussler

syndrome is a very rare transmissible disease, familial occurrence could have been interpreted as being due to pre- or perinatal infection with an unknown agent. The new linkage data show that a genetic component is essential for acquisition or manifestation of the disease.

A more fascinating consideration is that if the two families that suffer the syndrome are, as suspected, unrelated, and the identical PrP mutations arose independently, the amino-acid substitution would not only represent a genetic marker but also play an essential role in pathogenesis. This interpretation is strongly supported by an impending report describing two unrelated Japanese families with the ataxic syndrome that show the same proline-to-leucine substitution<sup>18</sup>. It could be argued in the 'protein only' hypothesis that the amino-acid replacement greatly increases the probability of spontaneous conversion of  $\text{PrP}^{\text{C}}$  to (an as yet putative)  $\text{PrP}^{\text{GSS}}$  which would then behave like a transmissible agent (it will be interesting to learn whether in these heterozygous patients  $\text{PrP}^{\text{GSS}}$  contains only the protein with the amino-acid substitution). One might further argue that in sporadic cases of Gerstmann-Sträussler syndrome and Creutzfeldt-Jacob disease a somatic mutation gives rise to a variant  $\text{PrP}$  with enhanced capacity to convert into  $\text{PrP}^{\text{GSS}}$  or  $\text{PrP}^{\text{CJD}}$ .

Although the new results<sup>2</sup> tip the scales in favour of the protein only hypothesis, they do not exclude the possibility that a nucleic acid is part of the prion. Taking into account the occurrence of sporadic cases of the diseases, such a nucleic acid or prion would have to be widespread in the population, but with low penetrance in the absence of predisposing PrP mutations. Ultimately, the question as to the nature of the prion should be resolved by generating infectivity *in vitro*, either from pure, non-infectious  $\text{PrP}^{\text{C}}$ , from a nucleic acid, or from a combination of the two. □

# Observations beyond the limit

Demosthenes Kazanas

CYGNUS X-3 is one of the brightest and most extraordinary objects in our Galaxy. It was first discovered as an X-ray source in 1966 and identified as the source of a giant radio outburst in 1972. Subsequent observations of Cyg X-3 have heralded the extension of the energy range for astronomy first to teraelectron volts (1 TeV =  $10^{12}$  eV) and then to petaelectron volts (1 PeV =  $10^{15}$  eV). Now Cassidy *et al.*<sup>1</sup>, using the 'Fly's Eye' detector in Utah, have observed Cyg X-3 at higher energies still — exaelectron volts (1 EeV =  $10^{18}$  eV) and above. The authors estimate the probability that the excess of cosmic rays at this energy observed from the direction of Cyg X-3 could occur by chance in a uniform distribution of showers is only  $6 \times 10^{-4}$ .

Collisions of high-energy primary cosmic rays in the upper atmosphere initiate showers of secondary particles which can be observed by astronomers. The Fly's Eye detector used by Cassidy *et al.*<sup>1</sup> maps the nitrogen fluorescence excited in the atmosphere by such showers and has a coverage of  $2\pi$  steradians. Since November 1986, the operation of two such detectors has permitted three-dimensional reconstructions of the showers. The TeV cosmic rays are observed via the Cerenkov (electromagnetic shock wave) radiation emitted by charged secondaries. And PeV rays initiate showers of electrons (and muons) observed directly by detectors on the ground. Each technique has a resolution of  $1^\circ$ , so that point sources can be identified.

## Interest and scepticism

Since its introduction in the early 1980s the field of astronomy at energies above 1 TeV has been viewed with both interest and scepticism<sup>2</sup>. The interest stems from the apparently counterintuitive fact that a large fraction (a tenth) of the luminosity of galactic accreting objects is emitted at energies above 1 TeV — well above the potential energy at the surface of even a neutron star — and in some cases up to 1,000–10,000 TeV. The scepticism arises from the rather low statistical significance of the observations owing to the small number of particles arriving from these sources at these energies: at such high energies, only a few particles are needed to contribute significantly to the total luminosity of an object. It was hoped that new larger detectors would settle the difficulties with statistical significance.

Unfortunately, observations of Cyg X-3 with one of these detectors reported recently<sup>1</sup> provide only upper limits to the flux at PeV energies, and the observers arrived at the unsatisfactory conclusion

that PeV emission ought to be episodic. This conclusion is nonetheless strengthened by observations of another source, Her X-1, an X-ray pulsar (period 1.2378 s), which has also been detected in the TeV and PeV range<sup>3,6</sup>. These observations indicate that at energies of 1 TeV or more, the signal from this source appears in bursts lasting anything from a few minutes to a hundred. A search for periodicities in these bursts indicates a period of 1.2357 s — an intriguing result, as this is significantly different from the period of the X-rays. To compound the puzzles, the muon content in the PeV showers is inconsistent with the assumption that they are initiated by photons (if they were, there should have been ten times fewer muons).

Instead, the muon content is consistent with that expected from hadron-initiated showers. But any such particles, if electrically charged, would be disturbed while traversing the turbulent interstellar magnetic field, so that the observed directional and temporal coherence of the showers could not have been preserved. And there are no known stable neutral particles that could fit the description.

Amid all these puzzles and problems there has been a significant recent advance which may put the whole field on a much firmer ground<sup>7</sup>: the detection of a statistically highly significant (nine-standard-deviation), constant signal of 1-TeV photons from the Crab nebula (background showers initiated by cosmic-ray hadrons were identified and subtracted). This is by far the most significant very-high-energy detection and was achieved by imaging the showers' Cerenkov radiation, a technique which allows the rejection of 98 per cent of the background events. The importance of this result lies in that it provides a weak ( $10^{34}$  erg s<sup>-1</sup>) but steady 'standard candle' against which future experiments will be calibrated.

What can be learned from all these observations? First, a large fraction of the accretion energy in many X-ray sources is converted (albeit sporadically) into relativistic protons with energies greater than 1 TeV (it is generally agreed that it is too difficult to accelerate electrons to these energies) which subsequently produce the observed high-energy radiation through nuclear collisions. Several models for these sources have been proposed (see ref. 8 for a review) which, however, are rather unconstrained owing to the scarcity of photons and lack of repeatability of the observations. Their most important feature is the estimate of the maximum energy expected (about  $10^{16}$ – $10^{17}$  eV) by the acceleration mechanism favoured by each model (shock acceleration near the

compact object or large-scale static electric fields).

Given their simplicity, the agreement of these models with the observations in the  $10^{15}$ – $10^{16}$ -eV range is rather remarkable. With the maximum particle energy already set by the models, it would seem that the new observations of Cassidy *et al.*<sup>1</sup> are in direct conflict with theory, especially if the observed particles are photons, which would have to be generated at the source by particles of energy  $10^{19}$  eV. Cassidy *et al.* point out, however, that the observed showers could be due to neutrons. (The Fly's Eye cannot distinguish between photon- and neutron-induced showers; also neutrons, although unstable, can get to Earth at these energies without much attenuation from decay.) Indeed, Ellison and I have proposed<sup>9</sup> that neutrons are copiously emitted from these objects and could be observed on Earth.

## High-energy tail

Furthermore, if the spectrum of the protons accelerated in the source decreases exponentially above the energy of maximum intensity suggested by the current models ( $10^{17}$  eV), the energy flux at 1 EeV should be  $\exp(10) \approx 10^4$  times smaller than that at lower energies, in rough agreement with the observations obtained with the Fly's Eye. These observations might therefore probe the high-energy end of the particle distribution that produces the radiation at PeV energies.

As for the muon content of the showers, the situation remains confused. An obvious solution is an unknown strongly interacting particle; more appealing, to my taste, is the recent proposal<sup>10</sup> that the quantum-chromodynamic structure of the photon causes an increase in the photo-production cross-section for particle collisions at energies of 0.5 TeV in the centre of mass. At these energies, the photons can interact with nuclei in the atmosphere by the nuclear strong force, a process which may compete with the electromagnetic ones considered so far in the shower development and enhance the muon content. These showers might hence be pointing to new physics at these energies, to be investigated with further observations and detailed modelling. □

## GRAVITATIONAL PHYSICS

## Fifth force remains elusive

Christopher Stubbs

COULD there exist a fundamental interaction that has until recently escaped detection? This notion was addressed at a recent workshop\* where participants assessed the current status of the 'fifth force'. The geophysical evidence for a violation of the inverse-square law of gravitation, one way such a force could be manifested, emerged weakened from the meeting, and the results reported from experiments investigating the universality of free fall were in accord with Newton's hypothesis. Nevertheless there remain some tantalizing indications that a new force exists, and given the advances made in the past year the consensus was that experimental effort should continue.

The suggestion 3 years ago<sup>1</sup> of a previously unobserved fifth force prompted a flurry of experiments designed to test the idea. Two types have so far been performed: tests of the weak-equivalence principle comparing the forces exerted on two different substances by some attractor; and geophysical tests of the inverse-square law that seek deviations from the newtonian prediction in the vertical gravity profile. Results are typically expressed in terms of a 'Yukawa' modification to newtonian gravity

$$V_s = a \left( \frac{q_s}{\mu} \right) \left( \frac{q_s}{\mu} \right) G \frac{M_1 M_2}{r} e^{-r/\lambda}$$

where  $\lambda$  and  $\alpha$  are the range and dimensionless strength of the interaction and  $GM_1 M_2/r$  is the familiar newtonian expression relating the gravitational potential between two masses  $M_1$  and  $M_2$  to their separation  $r$  and the gravitational constant  $G$ .

The relevant 'charge' per atomic mass unit  $q_s/\mu$  is generally assumed to be some linear combination of  $B/\mu$  and  $L/\mu$ , with  $B$  and  $L$  baryon (nucleon) and lepton (electron) number for the material, respectively. Experiments testing the equivalence principle compare the accelerations of materials presumed to differ in  $q_s/\mu$ ; and the geophysical measurements seek the effects of the exponential term in the potential. The original fifth-force hypothesis favoured  $q_s=B$ ,  $\alpha \approx 0.01$  and  $10 \text{ m} < \lambda < 1,000 \text{ m}$  (see the discussion by De Rújula in News and Views<sup>2</sup>).

Statistically, the most significant geophysical evidence for a departure from newtonian gravity comes from measurements of  $g(z)$ , the vertical profile, up a 600 m television transmission tower<sup>3</sup>. It is claimed that these measurements differ from the newtonian prediction calculated from an array of surface gravity measure-

ments. These tower data indicate an additional attractive coupling rather than the repulsive force consistent with earlier  $g(z)$  observations made in a mineshaft in Australia<sup>4</sup>. However, D. Bartlett and W. Tew (Univ. Colorado) question whether local topography was properly taken into account in the tower experiment, prompting the experimenters carefully to re-examine their data (D. Eckhardt, USAF Geophysical Lab.). In fact the surface gravity measurements were obtained at locations whose mean elevation differed from that of the actual terrain. Correcting for this has reduced the maximum discrepancy between the modelled and observed  $g(z)$  from  $550 \mu\text{gal}$  to  $350 \mu\text{gal}$  ( $1 \text{ gal} = 1 \text{ cm s}^{-2}$ ). Preliminary results from two other tower experiments (T. Niebauer and C. Speake, Univ. Colorado; P. Kasameyer and J. Thomas, Lawrence Livermore National Laboratory) appear so far to support conventional physics. The task of computing newtonian gravity properly is now generally recognized as the most delicate aspect of these experiments, particularly when assigning uncertainties to the prediction.

Gravity measurements performed down the 2,000-m Dye 3 borehole in Greenland were extensively reported last autumn when the preliminary analysis seemed to indicate a departure from the inverse-square law. The experimenters now report that although the borehole  $g(z)$  data (discussed by M. Gorman, Cambridge Univ. and R. Hughes, Los Alamos National Laboratory) disagree with the group's initial newtonian prediction, this discrepancy could well be the result of an intrusion of higher-density

material ( $\Delta\rho \approx 0.3 \text{ g cm}^{-3}$ ) in the rock below the ice cap. The likelihood of such an intrusion is much debated, even by members of the team itself. The group used an optimization code to determine the mass distribution of minimum  $\Delta\rho$  that could account for the  $g(z)$  data while remaining consistent with surface gravity observations. Applying a similar analysis to the gravity data available from the tower and mineshaft measurements (some are proprietary) has led to the claim (R. Parker, Scripps Institution of Oceanography) that the observed  $g(z)$  discrepancies in those experiments can also be attributed to an appropriate local distribution of higher-density material. This suggestion is currently being explored by the experimental teams.

Among the experiments testing the equivalence principle, two<sup>5,6</sup> have produced results consistent with a new material-dependent interaction, but others<sup>7-9</sup> saw no such effects. These initial composition-dependence results were contradictory when interpreted in terms of  $q_s = B$  (see News and Views articles published at the time<sup>10,11</sup>). Efforts have recently been focused on approaches for reconciling the positive observations with the null results, and on extending the search by using apparatus with increased sensitivity.

The suggestion<sup>6,12</sup> that a coupling to  $q_s = B - 2L$  (or isospin) could effect a reconciliation of the composition-dependence results has been closely inspected. This isospin picture amounts to supposing that the neutron and proton are endowed with 'charges' of opposite sign but equal magnitude. Because the Earth's crust (the attractor in the early experiments) is composed mainly of materials (silicon and oxygen) with equal abundances of neutrons and protons, the net  $q_s$  of the various experimental sites would depend on the detailed chemical composition of the local rock.

This hypothesis is readily tested by using either a proton-rich or a neutron-rich substance as the attractor, instead of terrestrial material. One such experiment has been performed by our Eöt-Wash group at the University of Washington, by comparing the interactions of beryllium and aluminium with 1.3 metric tons of lead. We have just published<sup>13</sup> a null result that excludes (at 2 standard deviations) the isospin picture for all scale lengths over which the positive results have been interpreted ( $10 \text{ m} < \lambda < 1,000 \text{ m}$ ).

Preliminary results presented at the meeting from a similar experiment (R. Newman and P. Nelson, Univ. California, Irvine) yielded a comparable upper bound. Another interesting experiment<sup>14</sup> used a torsion balance near a lock on the Snake River in the United States. The quantity of water acting on the balance was varied by the periodic filling and

FIG. 1 Constraints on a fifth force coupled to isospin, for  $\lambda = 100 \text{ m}$ . Allowed values of  $\alpha$  ( $\lambda = 100 \text{ m}$ ) are plotted as a function of  $\theta_s$ , where  $q_s = B \cos \theta_s + L \sin \theta_s$ . A coupling to 'isospin' corresponds to  $\theta_s = -63.4^\circ$ . The shaded region shows the area of agreement between the composition-dependence experiments. However, this is now of dubious significance given the lead-attractor results reported by the Eöt-Wash<sup>13</sup> and Irvine (Newman) groups. A slightly less stringent constraint is shown by the lock experiment of Bennett<sup>14</sup>.

\* XXIV Rencontres de Moriond: Tests of Fundamental Laws in Physics Les Arcs, Savoie, France, 21-28 January 1989.

FIG. 2 Constraints on the strength (relative to G) of a Yukawa interaction coupling to  $B$ , for ranges  $\lambda$  between 1 mm and  $10^{13}$  m. The positive results are shown as the shaded regions labelled 4, 5 and 6, in accord with the references. T denotes the best single-Yukawa fit to the revised tower data of Eckhardt *et al.*, who are still in the process of determining uncertainties. For clarity only the most stringent of the many null results are shown, which preclude values of  $\alpha$  greater than the corresponding constraint curves. Bounds that predate the fifth force controversy (see ref. 2) arise from laboratory  $1/r^2$  tests (Lab), from comparisons of the orbits of manmade satellites with that of the moon (Sat), from the precession of Mercury (Mer), and from the equivalence principle experiment performed in Moscow by Braginskii and Panov (Mos). Line 9 is from the freefall experiment of Niebauer *et al.*<sup>9</sup>, and 13 from the Eöt-Wash torsion balance experiment<sup>13</sup>. The dashed segments EW and Bi show the results reported at Moriond by the Eöt-Wash group and by Bizzeti *et al.*

emptying of the lock. The data analysis sought any deflection of the balance that was correlated with water level, and none was found. Results from these isospin experiments are presented in Fig. 1.

New data were presented from two terrestrial-attractor equivalence-principle experiments. A floating-sphere experiment reminiscent of the earlier one by Thieberger<sup>5</sup> was performed on a large-scale escarpment in Italy, by P. G. Bizzeti and collaborators (Univ. Firenze). After a careful search for systematic errors, the experimenters concluded that there was no discernible difference between the hillside's action on the submerged nylon sphere and its influence on the surrounding water. The upper limit on the horizontal acceleration difference of the two materials is  $2.4 \times 10^{-9}$  gal. This null result is particularly significant for  $1.5 \text{ km} < \lambda < 16 \text{ km}$ .

My colleague E. Adelberger presented preliminary hillside results that our team has obtained with a much improved version of our torsion balance. We observe no acceleration difference between beryllium and aluminium at the level of  $4 \times 10^{-11}$  gal, establishing the most stringent limit thus far on a composition-

dependent interaction for  $10 \text{ m} < \lambda < 1.5 \text{ km}$ . The current experimental limits on  $\alpha(\lambda)$  are shown in Fig. 2, with the various results interpreted in terms of  $q_s = B$ .

The initial fifth-force hypothesis of an intermediate-range interaction with  $q_s = B$  is not consistent with experiment. In fact no physically reasonable phenomenological model advanced to date can account for all the data, which is not too surprising given the apparent contradiction in the results.

Applying Occam's razor to the positive observations leads to the suspicion that there are unappreciated sources of systematic error in one or more of these delicate and demanding experiments. It should nevertheless be remembered that only one of the positive observations need be convincingly verified for there to be evidence of new physics. Theorists have shown that a feeble intermediate-range interaction could come about in various ways,

and could be readily accommodated in several pictures of the world beyond the standard model. The possibility that these experiments may provide a window into physics that is well outside the reach of any existing or planned accelerator is sufficient motivation to continue the search. □

## Digital puppetry

TELEVISION transmission is absurdly inefficient. A TV picture is retransmitted in its entirety about 30 times a second, taking up about 6 megahertz of bandwidth; the new high-definition format will need 30 megahertz. Yet the incremental optical changes could probably fit comfortably into a mere few kilohertz.

So Daedalus's new Electronic Theatre TV system makes no attempt to transmit a picture. Like the human perceptual system, it codes the scene as a physical model: a 'set' or 'backdrop' with a specified appearance, in front of which a 'cast' of objects (furniture, people, cars) stand or move in a specified sequence of positions. From this description, together with defined lighting and camera position, an image-reconstruction routine in the receiver works out what the scene must look like, and displays it.

Transmission bandwidth is utterly minimized. The transmitter downloads its backdrop and cast of characters only once per scene, like a word processor downloading to a printer the font in which a document is to be printed. Thereafter 'stage directions', simple sequences of spatial coordinates and details of changes of appearance, suffice to update the image. Massive real-time computing effort is needed both at transmitter and receiver; indeed, the scheme stretches existing technology to its limits. But since computing speed and power are increasing at a hectic pace, while communication bandwidth (especially geostationary-satellite bandwidth) is ever more scarce and costly, Electronic Theatre should soon be commercially feasible.

The new system will change production methods as well as transmission. Producers and playwrights will increasingly by-pass the camera and studio altogether. They will write a show or a play directly as a script of stage directions — calling up backdrops and casts from stock digitized libraries, manoeuvring them in program form, and studying the resulting visual effect. Viewers, too, will gain. A television set will be able to substitute a local 'font' of items and characters into any broadcast: turning a global soap-opera, for example, into a national, or even a family, story. The chilling uniformity threatened by global TV will be mitigated. Mischievous viewers who want their news read by Mr Gorbachev in drag, say, will also have their wish. And like the live theatre itself, an Electronic Theatre production can be endlessly renewed and re-interpreted. Old dramas will be re-set in different locations, transferred to nostalgic eras, or equipped with exotic characters. Electronic Theatre will not only release bandwidth for thousands of new channels: it will provide the semblance of variety to fill them. David Jones

# Are comet spins primordial?

SIR—Ferrin<sup>1</sup> contends that several comets, including Halley, rotate at rates determined during their primordial accretion. He bases this on the fact that comets satisfy  $L/M \approx M^{2/3}$  ( $L$  is spin angular momentum and  $M$  is mass), a relation approximately fulfilled by virtually all other solar system members. From this, he infers very low densities  $\rho$  for several comets.

Here, I argue that (1) the  $L/M$  relation indicates only that spin periods  $T$  of most Solar System members are about the same; (2) deviations from the constant-spin rule in other small Solar System bodies can be attributed to current processes; (3) the spin rates of asteroids and comets have been significantly altered by collisions and outgassing, respectively, and are thus not primordial; and (4) the  $L/M$  relation, although perhaps useful as a crude guide, is not a reliable indicator of density for a specific object.

For a homogeneous rotating sphere,  $L/M = 0.97M^{2/3}/(TQ^{1/3})$ ; a similar expression is known for triaxial ellipsoids<sup>12</sup>. Thus, if density differences between different celestial bodies can be ignored, the observation that  $L/M \approx M^{2/3}$  implies that rotation periods of Solar System members are roughly the same,  $\sim 8$  h, as originally noted for 70 asteroids and most planets<sup>2</sup>.

Rotation periods of cometary nuclei are poorly known because the classical halo method<sup>3</sup> and precession model<sup>4</sup> are of unproved accuracy. Except for Halley's case, the only reliable values come from recent CCD observations of three cometary nuclei<sup>5</sup> whose rotation periods are 12–22 h, significantly shorter than the 30–50 h periods Ferrin used. As cometary data are so scant, one might ask whether the spins of other small Solar System objects say anything about their beginnings.

The spins of almost 500 asteroids are now known<sup>6</sup>. All but 1–2% have periods within a factor of 3 of the mean,  $\langle T \rangle \sim 9$ –10 h, similar to most planets, a few nontidally despun satellites, and probably not too far from cometary periods. Furthermore, the considerable variations in asteroidal spins with their size<sup>6</sup> belies Ferrin's claim that celestial rotations are fixed primordially. The data show that: (1) large asteroids (radius  $R \geq 62.5$  km) have  $\langle T \rangle \approx 7.5$  h and a maxwellian distribution of spin rates, implying that collisions are important; (2) minor planets with  $R \approx 40$ –50 km spin more slowly ( $\langle T \rangle \approx 11$  h), a fact generally ascribed to angular momentum drain<sup>7</sup>; (3) the smallest asteroids ( $R < 15$  km) rotate faster in the mean ( $\langle T \rangle \approx 8.5$  h) but also have a wider dispersion, especially showing an excess of

slow rotators; they do not obey a maxwellian distribution, perhaps indicating their birth in catastrophic disruption events<sup>8</sup>; (4) spin characteristics also vary with asteroid taxonomy, with M-asteroids, presumed to be metal-rich and relatively dense, rotating fastest<sup>9</sup>.

Small asteroids and comets have had significant angular momentum imparted to them over the aeons. For the former, simple particle-in-a-box calculations<sup>8</sup> find frequent mutual collisions, both erosive and catastrophic, that re-set rotation rates, especially those of the tiniest asteroids. In contrast, comets rarely encounter a compatriot in the spacious Oort cloud nor often meet other projectiles during their brief sojourns within the inner Solar System, so collisions do not appreciably alter their angular momentum. Asymmetric outgassing may however induce comets to twirl faster or slower. The same gas jets that cause the non-gravitational accelerations of cometary orbits produce torques capable of modifying spins. Taking the tangential outgassing reaction force to be  $10^{-6}$  of solar gravity<sup>9</sup> and, for a lower bound on de-spin time, considering this force to have a moment arm  $R$ , spin rates are found to change dramatically over only a few orbits. A similarly swift de-spinning comes from estimating the angular momentum carried away by the sublimated gas. Because expansion velocities in jets are a few hundred  $\text{m s}^{-1}$  whereas typical surface speeds are  $\sim 1$   $\text{m s}^{-1}$ , much less than one per cent of the comet's mass, if lost tangentially to the surface, could remove the body's spin angular momentum. Such a mass is expelled in just a few passes by the Sun.

The rough rule that celestial objects — whether asteroids, comets or pulsars — spin faster when they are denser simply manifests the greater ability of compact objects to hold themselves together as they are spun up. Equatorial surface layers on solid spheres become centrifugally unbound once  $T \leq 3.3$  ( $\rho/g \text{ cm}^{-3})^{-1/2}$  h (refs 2,3,5) while debris on the most distant tips of triaxial bodies will be lost at even slower rates<sup>2</sup>. Loosely bound agglomerates (rubble piles), such as sometimes proposed for comets<sup>11</sup>, flow and elongate at spin periods less than  $\sim 6$  ( $\rho/g \text{ cm}^{-3})^{-1/2}$  h (ref. 12).

Whether one looks at Solar System rotation data in terms of a constant spin-rate law or some universal  $L/M$  plot, one should not take the results too literally. While appearing profound,  $L/M$  relations, which also seem to apply to other classes of astronomical objects, have been dismissed<sup>13</sup> because they merely reflect reasonable upper and lower limits on orbital and/or spin rates, much as I maintain above. Furthermore, data that look so

remarkable on log-log plots over many orders of magnitude in the mass actually show considerable scatter of individual points. As an extreme example, 288 Glauke, an 18.5-km S-object, takes 1,150 h to rotate while the comparable asteroid 321 Florentina spins in 2.87 h; are we to conclude that their densities differ by a factor of 8,000?

These arguments show that the observed rotations of comets and small asteroids are not primordial. Instead, their spins probably result from a partly delimited evolution. Torques, which act sporadically to spin these bodies up or down, cannot produce very rapid rotations because of the centrifugal breakup limit; the end result is that spins are always found somewhere between zero and this limit. Clearly for asteroids, rotation rates do hint at processes of angular momentum transfer. But too little is now known about cometary rotation for cometary origins or properties to be valuably constrained.

On the other hand, it may be that, as the Duchess in *Alice in Wonderland* believed, "If everybody minded their own business, the world would go round a great deal faster than it does."

## On *Prochlorothrix*

SIR—In his News and Views article<sup>1</sup>, David Penny noted the conflicting results of two comparative biochemical studies of *Prochlorothrix* and other photosynthetic prokaryotes — a study by Turner *et al.*<sup>2</sup> on the 16S ribosomal RNA subunit and a study by Morden and Golden<sup>3</sup> on psbA, a photosystem II-associated protein. Turner *et al.* place *Prochlorothrix* close to *Synechococcus* in a separate line of descent from green chloroplasts, whereas Morden and Golden suggest a closer relationship between green chloroplasts and *Prochlorothrix*. Although these results are inconsistent, it should be noted that both studies<sup>2,3</sup> are a preliminary part of the effort to place the Prochlorophytes on the basis of the limited amount of available

experimental data. The lack of information about possible polymorphisms in natural populations, for example, is an issue which needs to be addressed by further study.

We would like to add that there is an important body of structural data which should be considered before lineage maps are drawn on the sole basis of a few nucleic-acid sequences. The photosynthetic membranes of green chloroplasts have a characteristic, well-studied structural organization, which includes a biochemical segregation of photosystems and other components into stacked (granal) and non-stacked (stromal) membrane regions<sup>5</sup>. Studies on *Prochloron* carried out by others<sup>6</sup> as well as our recent study<sup>7</sup> on *Prochlorothrix* indicate that surprisingly many of the structural details of photosynthetic membrane architecture are identical in green chloroplasts and prochlorophytes. In *Prochlorothrix*, these include membrane appression, an asymmetrical distribution of intramembrane complexes between stacked and non-stacked membranes, the sizes and shapes of particles in membrane fracture faces, and the existence of a tetrameric complex on the membrane inner surface which (in green chloroplasts<sup>8</sup>, at least) is associated with oxygen evolution.

The wealth of structural similarity between prochlorophyte and green chloroplast photosynthetic membranes suggests a much closer relationship between *Prochlorothrix* and *Synechococcus*. It also casts doubt on the ease with which one can suggest, as do Turner *et al.*<sup>2</sup>, that "the acquisition of the ability to synthesize chlorophyll *b* would not seem to be a significant biochemical change". Although the chemical differences between chlorophylls *a* and *b* are indeed minor, the similarities between prochlorophytes and green chloroplasts run much deeper than the aldehyde group of chlorophyll *b*. It is a major pattern of membrane architecture that they have in common, not just the possession of the same chemically modified form of chlorophyll *a*. The independent evolution, in two separate lines of descent, of nearly identical patterns of membrane appression, architecture and photosystem segregation seems, to us, unlikely.

## Sympatric pest

SIR—Three recent letters<sup>1–3</sup> and an accompanying News and Views article<sup>4</sup> concern the fascinating story of how, in the past 200 years, the native American fly *Rhagoletis pomonella* has apparently moved from its native hawthorne host to become an important pest of commercial apple crops. The assumption is made in all four papers that the clear genetic features characterizing the populations breeding on apples have arisen both sympatrically and very recently, evolving from a resident American population that originally infested only the native hawthorne. But an alternative, if less interesting, explanation for the genetic origin of this pest is also possible.

Before the introduction of the apple, there may have been two or more genetically distinct races of *R. pomonella*, adapted to different hawthorne species or possibly to an endemic native crabapple, such as *Pyrus coronaria*. One such population could have been preadapted for the exploitation of the commercial apple and could then have multiplied, with only minor genetic change, into the abundant pest as we know it today. The rapid sympatric evolution of a host race would not then be a required explanation; the transfer from hawthorne to apple could have been simple colonization of a newly available host.

The hawthorne genus (*Crataegus*) in the north central United States and adjacent regions of Canada consists of over a hundred taxonomically diverse and confusing species belonging to 19 series (species groups)<sup>5</sup>. There are additional varieties, hybrids and/or apomicts. At least 40 recognized species of *Crataegus* occur in the Michigan-Illinois region and more than 20 others are found in the limestone refugia to the south. These latter are ancient highlands that go back to the Permian. They were never covered by glaciers, nor were they ever flooded like the coastal plain or the inland sea. They were the source of most of the colonizers of the recently glaciated areas of Ohio, Michigan, Indiana and Illinois to the north<sup>6</sup>. *R. pomonella* has surely coexisted with many of this truly colossal number of hawthorne species for thousands — or even millions of years, moving south with the plants as the glaciers advanced and then moving back north as the ice retreated.

Must it be assumed that there were no

host races of *R. pomonella* formed during all this time but that a new one was formed in the past 200 years? Sympatric origin of host races is by no means a trivial matter, either for practical pest management or for evolutionary genetics. Accordingly, before accepting the evolution of a distinct host race that arose sympatrically in historic times, further data on the populations that breed on hawthornes must be sought.

## Our ancestors

SIR—Hominids and the African apes form a well-defined clade, but there is disagreement on the initial divergence of that clade. Most molecular evidence favours the gorilla as the first to diverge, whereas most morphological evidence puts hominids there. The second alternative is mildly supported by evidence from chromosomes<sup>1</sup>. The evidence in each direction is strong and is based on independent and internally complex data, which have been examined by Andrews<sup>2,3</sup> in an excellent review. Later work merely accentuates the problem, which exists primarily because it is taken as axiomatic that the point of divergence was the same for all characters. This need not, however, have been the case.

Perhaps all three groups diverged from the same species, which may have been geographically variable. If so, reassortment of the results of local evolution could produce conflicting apparent phylogenies if one looks at only part of the evidence. As a simple example, the diverse aspects of knuckle-walking and thinner enamel may have begun to evolve in a proto-gorilla subspecies and then been transferred to proto-chimpanzees after the latter mostly separated from proto-hominids.

Such a resolution of the problem is a bit awkward, but on existing evidence it is not as awkward as the alternatives<sup>4</sup>. It has no bearing on classification except to a cladist. Accumulation of further evidence like that now available would support the tritomy (or autotomy?). In contrast, establishment of a long initial divergence time, by fossil or molecular evidence, would make it implausible.

## Oncology

A. B. Miller, University of Toronto (Ed.)

### **Diet and the Aetiology of Cancer**

1989. 2 figures. VII, 73 pages.  
(ESO Monographs). Hard cover DM 92,-.  
ISBN 3-540-50681-0

This fine volume gives a concise review of current knowledge on the association between dietary fat and hormone associated cancers. Attention is focused on cancer of the breast, endometrium, ovary, prostate, and colorectum, although reference is also made to other cancers.

U. Eppenberger, University of Basel;  
A. Goldhirsch, Lugano (Eds.)

### **Endocrine Therapy and Growth Regulation of Breast Cancer**

1989. 26 figures, 17 tables. IX, 92 pages. (Recent Results in Cancer Research, Volume 113). Hard cover DM 98,-. ISBN 3-540-50456-7

The topics discussed in this text include: the comparison of in vitro cultures of epithelial cells with breast cancer cells, the effect of steroids and their antagonists, the involvement of suppressor genes in tumour progression, the modulation of transforming growth factors by estrogen, and prognostic factors such as cERB-2 and EGF-R in breast cancer.

P. Koldovsky, U. Koldovsky, L. Beck,  
K.-H. Vosteen (Eds.)

### **Lymphocytes in Immunotherapy of Cancer**

1989. 33 figures, 21 tables. XI, 100 pages. Soft cover DM 88,-. ISBN 3-540-50457-5

Research indicates that in the future, even better therapeutic results can be expected from combined approaches which include LAK cell therapy, and this book summarizes various approaches. The most important question is whether synergism or antagonism to other biological response modifiers plays a role in changing the immunological specificity of LAK cells.

## Endocrinology

E. E. Müller, D. Cocchi, V. Locatelli, University  
of Milan (Eds.)

### **Advances in Growth Hormone and Growth Factor Research**

1989. Approx. 400 pages. Hard cover DM 148,-.  
ISBN 3-540-19066-X

Readers of this book can update their knowledge in the fast-moving field of endocrinology and neurobiology. The important new findings are relevant to progress in pediatrics, pediatric and clinical endocrinology, neuroendocrinology and physiology.

Jointly published by Springer-Verlag Berlin  
Heidelberg New York London Paris Tokyo  
Hong Kong and Pythagora Press Rome Milan

A. Steinmetz, Lille; H. Kaffarnik, J. Schneider,  
University of Marburg (Eds.)

### **Cholesterol Transport Systems and their Relation to Atherosclerosis**

1989. 47 figures, 13 tables. XIV, 114 pages.  
(Recent Developments in Lipid and Lipoprotein  
Research). Soft cover DM 64,-.  
ISBN 3-540-50548-2

A number of clinical and epidemiological studies have shown that disorders of lipoprotein metabolism constitute one of the most important risk factors for the development of atherosclerosis and coronary heart disease. This volume examines the state of the art of lipoprotein subclass metabolism and its relation to these diseases.

G. Wolfram, University of Munich (Ed.)

### **Genetic and Therapeutic Aspects of Lipid and Purine Metabolism**

1989. 59 figures, 33 tables. XIII, 162 pages. Hard cover DM 98,-. ISBN 3-540-50408-7

Survey articles and original material contributed by leading scientists in Europe and the United States discuss genetic and therapeutic aspects of lipid and purine metabolism. Special interest will be captured by the comparison of all known plasmapheresis procedures for the treatment of acute hypercholesterolemia.

## Ternary Alloys

A Comprehensive Compendium of Evaluated Constitutional Data and Phase Diagrams

Edited by G. Petzow and G. Effenberg

This is the first systematic compilation of data on ternary alloys, starting with 184 ternary systems containing silver in Volume 1 and 262 silver systems described in Volume 2. The contents are arranged in alphabetical order of the chemical symbols of the constituent elements and have a uniform structure, so offering easy access for the specialist.

The compendium will prove indispensable to everyone concerned with the research and development of materials, such as materials scientists and engineers, metallurgists, chemical engineers, inorganic chemists and physicists.

The complete work will consist of ca 40 volumes.

### Volume 1: Ag-Al-Au to Ag-Cu-P

1988. XVIII, 612 pages with 376 figures and 156 tables. Hardcover. ISBN 3-527-26941-X

### Volume 2: Ag-Cu-Pb to Ag-Zu-Zr

1988. XVIII, 624 pages with 301 figures and 260 tables. Hardcover. ISBN 3-527-26942-8. Format: 28 cm x 28 cm. Single volume price £ 285.00 each, subscription price £ 250.00 each.

## Dechema Corrosion Handbook

12 large format volumes

2 volumes per year, volumes 4 and 5 in 1989

The Dechema Corrosion Handbook – a series of at least twelve large format volumes (21 cm x 28 cm) describes the corrosion behavior of technically important and often applied materials, and shows possible ways to prevent and fight corrosion.

The handbook is a comprehensive, reliable and up-to-date reference work not only for the construction engineer in the chemical industry but also construction and process engineers in other branches of industry as well as for materials scientists in research and teaching.

Approximately 350 pages per volume. Individual volume price: £ 286.00. Subscription price: £ 238.00.

## Advanced Materials

A Journal covering

Polymers · Ceramics · Composites · Metals · Alloys · Intermetallics · Semiconductors · Conductors · Superconductors · Catalysts · Sensor Materials · Biomedical Materials · Colloids · Thin Films · Liquid Crystals

1989. Volume 1. Published monthly. Annual subscription rate £ 68.00.

Krasovitskii, B. M. / Bolotin, B. M.

## Organic Luminescent Materials

1988. XI, 340 pages with 52 figures and 15 tables. Hardcover. £ 67.00. ISBN 3-527-26728-X

This practical guide familiarizes its readers with techniques for the synthesis of luminophors, explains their luminescence properties and describes numerous applications. It helps chemists to concentrate their efforts on the synthesis of luminophors that are of practical value.

## A Guide to Materials Characterization and Chemical Analysis

Sibilia, J. P. (ed.)

1988. X, 318 pages with 204 figures and 1 table. Hardcover. £ 25.95. ISBN 3-527-26867-7

Written both for the novice and for the experienced scientist, this miniature encyclopedia concisely describes over one hundred materials methodologies, including evaluation, chemical analysis, and physical testing techniques. Each technique is presented in terms of its use, sample requirements, and the engineering principles behind its methodology.

# Great expectations

Hans Primas

**Beyond the Atom: The Philosophical Thought of Wolfgang Pauli.** By K.V. Laurikainen. Springer-Verlag: 1988. Pp. 234. Pbk DM68, £22.50, \$29.

WOLFGANG Pauli (1900–1958) was a revolutionary genius, a most critical theoretical physicist with profound insight, and a deep thinker. He was an infant prodigy — at the age of 18 he was in full possession of the mathematical and physical knowledge enabling him to do original research on general relativity. At 21 — still a student — he published in the *Encyklopädie der mathematischen Wissenschaften* his masterly review article on relativity theory, which was greatly admired by Einstein himself. Later he became renowned for his fundamental work and brilliant reviews on quantum mechanics and quantum field theory.

Pauli has been called “the living conscience of theoretical physics”, “der fürchterliche Pauli” and “god’s whip” because he attacked every half-truth with pitiless severity. But his criticism was always sound and came to be relied upon. In Pauli’s view, there was no basis for the type of unified field theory pursued by Einstein. But in spite of this and other deep epistemological disagreements, the old Einstein held Pauli in high esteem and called him his spiritual son.

Although Pauli is recognized as one of the leading theoretical physicists of the twentieth century, his long-standing philosophical efforts and penetrating jungian studies are less well known. Only a few of his published articles deal with epistemological problems — the technical papers are remarkably free of philosophical comments. But this state of affairs gives an entirely misleading impression of Pauli’s wide range of philosophical and historical interests, and his far-reaching commitment to jungian thought. Professor Laurikainen’s *Beyond the Atom* — in the main a translation of his Finnish book *Atomien Tuolla Puolen* of 1985 — will, one hopes, change things. The book is based on the extensive but yet unpublished correspondence between Pauli and Markus Fierz, Pauli’s former postdoctoral assistant (1936–1940) who at the time was professor of theoretical physics in Basle.

Pauli took up the psychophysical problem by studying the connection between the complex psychology of Carl Gustav Jung and modern physics. In particular, he investigated the archetypal background of physical concepts, and published a remarkable case study on the genesis of scientific theories in the light of the historical controversy between the trinitarian point of departure of Kepler’s astronomy and Fludd’s quaternarian

alchemical viewpoint. Quaternity is taken to be an expression of all concepts of unbroken totality, both in psychology and in physics. The “quaternarian attitude” (an expression often used by Pauli in his letters) is not easy for a classical scientist to grasp. Pauli and Jung discussed the conjecture that the statistical method of natural science could be in a complementary relationship to synchronicity, in the sense that any statistical description excludes synchronistic phenomena. They proposed that the triad of energy, space-time and causality should be complemented by the synchronicity factor to arrive at a “quaternion”, which stands for the unity of being.

In order to express this idea of an unbroken unity, Pauli was looking for a

new conceptual language between the physical and archetypal domains, a language that was neutral with respect to the distinction between physical and psychological phenomena. He conjectured that the alchemistic attempt to create a unitary psychophysical language failed merely because it dealt with a visible reality, and he hoped that the same programme, referring instead to a deeper invisible reality, could be successful. That is, Pauli was striving for nothing less than a coherent and unified conception of the world, in which natural science would be just a part, and which would allow an understanding of matter and psyche as complementary aspects of the same reality — a reality containing both rational and irrational elements. Because the logical structure of complementarity has become transparent within the mathematical formalism of quantum mechanics, it is not so extraordinary that it is just theoretical physicists who have recognized the road sign and have taken up the investigation of complementary relationships outside natural science.

According to Laurikainen, the Pauli-

Wolfgang Pauli — “striving for nothing less than a coherent and unified conception of the world”.

Fierz letters are the best source for the study of Pauli's philosophical views. In his book, he lets Pauli speak for himself in long quotations from the correspondence, unfortunately without Fierz's answers. Laurikainen's selection of material and his analysis of it unavoidably reflect his own tastes and inclinations, but these limitations cannot lessen my regard for his well-thought-out presentation. The most important message of the book is that if we take Pauli's view seriously, we have to re-evaluate fundamental questions in natural science and ponder about the repression of the irrational in Western culture.

With respect to some details, I found myself repeatedly disagreeing with Laurikainen. Fortunately, this disagreement is mainly about questions of present-day quantum mechanics, which was not an issue in the Pauli-Fierz correspondence. Laurikainen believes that Pauli would not have agreed with modern foundational research on quantum theory and the current attempts to generalize quantum theory and to apply it to the meso- and macroscopic domain. To my mind it is wrong to pass such a judgement on the basis of the Pauli-Fierz letters.

In the correspondence, Pauli argued that the general trend of Western culture after the seventeenth century has been dangerously one-sided. He considered the cartesian separation of spirit (*res cogitans*) and matter (*res extensa*) to be misconceived and preferred a vision where spirit and matter are considered as two complementary aspects of reality. Pauli was looking for radically new ideas which went far beyond the limits of quantum theory. According to him, the possibility of free choice of the experimental set-up implies that observations acquire the character of the irrational, unique actuality. But he also stressed that "the psychic state of the observer enters the laws of nature of quantum mechanics no more than those of classical physics", and that "the old question whether the psychic state of the observer possibly may influence the external material evolution of Nature, has no place in contemporary physics". We have to acknowledge that there is a lacuna in the reasonings of present-day physics. Pauli tried to open up new paths, but his programme was very ambitious and remains rather vague, so we cannot implement it in our current theoretical framework. As Pauli himself wrote, the problem is that we must not thereby sacrifice the positive values of the trinitarian attitude. I think that Laurikainen sometimes misconstrues Pauli's vision of a unitary theory as being a comment on present-day quantum mechanics.

**"The most important message of the book is that if we take Pauli's view seriously, we have to re-evaluate fundamental questions in natural science and ponder about the repression of the irrational in Western culture."**

I have one further reservation, also minor. Laurikainen has tried to make Pauli's philosophy understandable to an average academic reader, not only to scientists. Even for the committed reader it is at present the only generally accessible source of Pauli's philosophical correspondence; it is indeed an excellent guide to his views and gives a good first impression of the exchange of ideas with Fierz. But an essay of this nature can never be totally adequate. A full appreciation of Pauli's visions requires a substantial knowledge of quantum mechanics, of the history of ideas and of archetypal psychology. I suspect that most theoretical physicists, psychologists and philosophers who would like to grasp Pauli's ideas stand in need of much more help than they get here. Even Pauli looked for a helping hand — in an unpublished letter (not quoted

by Laurikainen), he expressed his disappointment about the lack of scientific education of Jung's circle, and his hope of finding a discussion partner with profound psychological insight and a good knowledge of mathematics and the natural sciences. So what we urgently need is a complete edition of Pauli's philosophical correspondence with explanatory notes written by various qualified scholars.

Moreover, there is much more pertinent material in the archives. A wealth of supplementary information can be found in Pauli's correspondence with Carl Gustav Jung, Marie-Louise von Franz and Aniela Jaffé, preserved at the ETH in Zurich. There are also related, unpublished manuscripts by Pauli — such as *Die Vorlesung an die fremden Leute*, or his important *Hintergrundphysik* (which is not lost, contrary to Laurikainen's suspicion) — and there is further correspondence, such as that with Heisenberg in the 1950s. Unfortunately, not all of the curators of these papers have allowed them to be published. It would be an intellectual disgrace if the legal heirs of the Pauli estate are allowed to suppress his visions and dreams (which in Pauli's own judgement unquestionably have an objective content), and publish only those letters that are 'relevant' to the history of physics, or that correspond with prevailing scientific fashions. I hope that the appearance of Laurikainen's ground-breaking and thought-provoking book will encourage the publication of a complete and annotated edition of all Pauli's letters and manuscripts in the near future. □

Hans Primas is a Professor in the Laboratorium für Physikalische Chemie, ETH, CH-8092 Zürich, Switzerland.

## The star worm

Paul Sternberg

### The Nematode *Caenorhabditis elegans*.

Edited by William B. Wood and the Community of *C. elegans* Researchers. Cold Spring Harbor Laboratory: 1988. Pp.667. \$94.

IN 1963, Sydney Brenner wrote in a proposal to the Medical Research Council:

Part of the success of molecular genetics was due to the use of extremely simple organisms which could be handled in large numbers: bacteria and bacterial viruses. ... We should like to attack the problem of cellular development in a similar fashion, choosing the simplest possible differentiated organism and subjecting it to the analytical methods of microbial genetics.

Brenner not only chose the nematode *Caenorhabditis elegans* as the organism, but encouraged a generation of scientists to join him; hence, 25 years on, the publication of this first-rate monograph which reviews the work of some 400 scientists. Besides summarizing the basics of *C. elegans* biology, the book presents in digestible form the main accomplishments — determination of the complete cell lineage and of the 'wiring diagram' of the 302-celled nervous system, and the collection of a genetically mapped set of ordered recombinant DNA clones (a genomic map) which is now over 60 per cent complete.

These projects have been carried out by and large at the MRC Laboratory of Molecular Biology, Mecca for *C. elegans* researchers. What then of the unlucky faithful who are unable to make the pilgrimage but who nonetheless want to participate now that the stage is set for a variety of fundamental studies of developmental, neuro- and molecular biology? By reading the book, one can learn much 'worm lore', as well as gain a sense of the excitement in the field.

A scientist starting work on *C. elegans* a decade ago would have had only a handful of publications to read; now one would confront a staggering number of important papers as well as a vast amount of unpublished data. In these days of chasing problems across diverse phyla, researchers often have to grapple unaided with the intricacies of a novel experimental system. Here is help for such people. For example, the often arcane details of the *C. elegans* field (*unc*, *Dpy*, *B.alapaav*, *HSN* and so on) are made accessible to anyone who wants to get to grips with them. The uniformly high quality of the chapters and the extensive cross-referencing not only reflect careful editing, but the cooperative effort of the authors and editor. A great deal of information is presented, however, and some work on the part of the reader is still required.

The application of molecular genetics to muscle, the nervous system and cell lineage is the hallmark of research on *C. elegans*, as is made evident in several cogent chapters. For example, the ability easily to identify and propagate paralysed mutants defective in a myosin heavy chain made possible the first complete sequence of this polypeptide. Identification of over 100 genes controlling various aspects of development relied on many of the characteristics apparent to Brenner in his choice of the worm, especially its small number of cells and short generation time. Yet although the excitement of recent work on sex determination and germline development is amply conveyed, a chapter devoted to the cuticle and molecular genetics of collagen would have been welcome — several genes defined by morphological and behavioural mutants

encode collagens.

The final third of the book is taken up with helpful appendices. The summary of methods is not a complete laboratory manual, but is a good place to start. A 60-page gene list includes invaluable information for the novice (or expert), such as how easy it is to score the phenotypes of the various mutants.

For any biologist, this monograph can serve as an enticement to study a favourite problem in the worm, or as a source of unanswered questions. One hopes that those so encouraged will retain the co-operative spirit, the high standards and the love of this organism that have characterized the field over the past two decades. □

Paul W. Sternberg is in the Division of Biology, California Institute of Technology, Pasadena, California 91125, USA.

## The number of the rose

John D. Barrow

**Between Quantum and Cosmos: Studies and Essays in Honor of John Archibald Wheeler.** Edited by W.H. Zurek, A. van der Merwe and W.A. Miller. Princeton University Press: 1988. Pp. 623. \$49.50.

"TIME is God's way of keeping things from happening all at once." Anyone who treasures this amongst their favourite aphorisms is clearly a little out of the ordinary.

John Wheeler is certainly such a person. In honour of his seventy-fifth birthday many of his former students and collaborators cornered six issues of the monthly journal *Foundations of Physics* and filled them with research papers and reviews on subjects to which Wheeler has made fundamental contributions or in which he has a strong interest. Here, these articles are gathered up into a single volume. The result is different both in style and intent from the earlier Wheeler *Festschrift*, *Magic without Magic*, published a decade ago. There are many more contributions, at a much higher technical level, and there are no general biographical articles about Wheeler's scientific career and style of working. Instead there are annotated highlights and characteristic artwork from his most important papers. Yet despite these adornments and the catchy titles of many contributions, this is not a popular book nor even one for scientific outsiders.

The articles fall into five principal categories. The first spans those areas of nuclear physics with a wheelerian pedigree; in particular, the development of the theory of fission (with Niels Bohr), the S-matrix, nuclear models and the role

of nuclear spin-orbit interactions down to the properties of positronium and electrodynamics. The bulk of the book deals with Wheeler's primary interest, gravitation — he was the first to introduce such topical concepts as black holes, wormholes, the Wheeler-de Witt equation of quantum gravity, together with the whole viewpoint of geometrodynamics. The quantum gravity articles in this selection form an interface with those on the interpretation of quantum measurement, where the Everett-Wheeler 'many worlds' interpretation provides the only way of looking at quantum mechanics that makes any sense of the concept of quantum cosmology. The articles by Dicke, d'Espagnat, Ne'eman, Unruh, Braginsky and Khalili, Wothers and Peres all deal with aspects of the quantum measurement problem.

The last and most interesting section of the book contains papers on the concepts of complexity and computation in their most abstract forms. Here there is a long and characteristically insightful discussion of quantum computation by the late Richard Feynman, in which he argues that there are no physical barriers to the reduction of the size of computers to the atomic scale where their mode of operation would become intrinsically quantum mechanical. Landauer and Bennett, two of the foremost contributors to the development of algorithmic complexity as a branch of physics, then each consider the notion of computation and complexity. They show how physics can subject the concept and process of computation to detailed analysis, in order to discover whether the Heisenberg uncertainty principle or the second law of thermodynamics place fundamental limits upon the scope and speed of computation. Bennett provides some discussion of the concept of 'logical depth' as an adjunct to the earlier definition proposed for the complexity of a sequence which used a purely quantita-

tive measure — the shortest program able to generate the sequence — because account must be taken of the difficulty of arriving at the minimal program. Some proposals for achieving this find their way into Bennett's contribution, although the best ideas, which concentrate upon the amount of entropy generated by the program of minimum length, were made after his article was written.

Finally, one should highlight the article by Geroch and Hartle, which describes what it means for a measurable physical quantity to be computable in the sense of Turing, Church and Post. In our mundane experience of physics, non-computable functions have not emerged naturally. It is, though, quite possible for the varieties of differential equation familiar in physics — ordinary differential equations or hyperbolic wave equations — to possess solutions which are non-computable functions of well-posed initial conditions, if one allows the initial behaviour to be not entirely smooth but contain creases and cusps like those found at the point of a cone. Although it is usual for physicists to discount such kinky starting conditions as physically unrealistic, it is not clear that they should do so given the non-continuum nature of classical physics.

Geroch and Hartle discuss a recently discovered example, which arises in quantum cosmology. Here, an observable is found to be equal to a sum of quantities, which must be evaluated for all the compact four-geometries. But the infinite list of these geometries is known to be non-computable. This does not necessarily mean that the observable cannot be computed and predicted — there might be another way that avoids listing the unlistable and so is computable. Nonetheless, it provides an interesting example of how difficult it may prove to answer some of the questions posed in cosmology and particle physics. The ultimate capability of the human brain and of all our computational machines may fall short of that required to rationalize things.

The book makes interesting reading, but it is disappointing in some respects. The articles were originally intended for a journal, and the authors might have written more generally, more speculatively and in a style suited for a wider audience had they set out to compile a book. Aside from the cache of contributions on computation, they show primarily what can be achieved by technical expertise rather than creative imagination. Because John Archibald Wheeler has displayed, and continues to display, the power of the imagination more powerfully than almost any other physicist, that is a pity. But perhaps it shows simply that only John Wheeler can write the articles that John Wheeler writes. □

## On the beach

Donald J.P. Swift

**The Morphodynamics of the Wadden Sea.** By Jürgen Ehlers. A.A. Balkema: 1988. Pp.397. DM 185, £52.75.

THE Wadden Sea is the intertidal zone of the German Bight of the North Sea. Varying in width from 10 to 50 km, it is an expanse of tidal channels, flats, inlets, flood and ebb deltas, barrier islands and estuaries that extends from Den Helder in the Netherlands to Blåvandshuk in Denmark.

Jürgen Ehlers explains that while mapping the geomorphology of the Wangerooge (map) sheet, "I came to realize the importance of both the major and minor bedforms of the Wadden Sea.... At the same time, my observations led me to suspect that the remodeling of the landscape [was occurring] at a much faster rate than I had previously assumed". With his consciousness thus raised, Ehlers initiated an aerial photographic survey of the Wichter Ee, a tidal inlet between the barrier islands of Norderney and Baltrum, over a 30-day period. The resulting analysis of shoal and megaripple migration forms the core of this book, but there is much more.

After chapters on barrier-island development, recent geomorphological processes, morphodynamic units and historical development, the author rolls up his sleeves and launches into a description, one by one, of the 35 barrier islands of the Wadden Sea and their associated intertidal terrains. This roll call of islands, from Fanø, Mandø, Rømø and Sylt in the North Frisian Islands, through Wangerooge, Spiekerooge, Langeoog and Baltrum in the East Frisian chain, to Terschelling, Griend, Vlieland and Texel in the West Frisian Islands, will for many readers constitute the real strength of the book.

The careful review of historical records is another valuable contribution. Eight centuries of documents allow us to shift from the time scale of fluid dynamical processes at seconds, minutes, days and years into the lower portion of the geological frequency band. Within these eight centuries we can resolve some of the event-dominated fine structure of the most recent phase of the Holocene transgression of the North Sea basin. Important loss of land occurred in the storm surges of the years 1010, 1020, 1041, 1075, 1094, 1102, 1114, 1164 and 1282. The greatest single land loss resulted from the surge of 16 January, 1362, the second Marcellus flood, also known as the *Grosse Mandränke* (great mandrowning). Jade Bay, the Dollart and Harle Bay were enlarged, and in Nordfriesland vast areas of

land disappeared under water, including the legendary Rungholt, east of the present island of Pellworm. A second *Mandränke* occurred on 11 October, 1694. But the main and partially enduring land losses, resulting in the formation of Jade Bay, the Dollart and the Zuider Zee, did not occur as the result of single events, but gradually, through many smaller stages. These land losses were due to a lack of technical infrastructure capable of protecting the vast forelands from the destructive effects of later surges in later decades. Land reclamation occurred, but only through projects that lasted for centuries.

It is important to appreciate this monograph for the fine work of descriptive morphodynamics that it is, and to avoid

viewing it as an indifferently designed work of other purpose. The author's skills lie in the collecting and ordering of information. Chapters that attempt to take an overview, such as those on natural preconditions and barrier-island development, are not altogether successful, although they are always interesting. On the other hand, the relentless procession of maps, aerial photographs and, above all, photograph after photograph at ground level, has a hypnotic effect. Somewhere through the 393 figures, these vistas of misty dunes, beaches and marshes, and of tidal flats extending to the horizon, seep into the unconscious—you have *been* there. □

## Nature explained

R. McNeill Alexander

**Life's Devices: The Physical World of Animals and Plants.** By Steven Vogel. Princeton University Press: 1988. Pp.367. Hbk \$49.50; pbk \$17.95.

WHY do starfish have five arms? Why don't animals run on wheels? And isn't it intriguing that spider silk has five times the strength of mild steel, and that prairie dogs (rodents, not canines) dig self-ventilating burrows? Here is a brilliant and eccentric book that looks at living things from an engineering point of view, assuming astonishingly little previous knowledge of science on the reader's part.

A summary of one chapter will give the flavour of the whole. Under the same weight of laundry, a sagging clothes line is less likely to break than a tight one. This helps us to understand why there is more tension in the wall of a large pipe than of a smaller one, when both contain fluid at the same pressure: automobile tyres need thicker walls than bicycle tyres (although the latter are inflated to higher pressure), and arteries need thicker walls than blood capillaries. Toy balloons do not inflate uniformly but start with a localized bulge, and blood vessels would be apt to swell similarly were it not for the peculiar properties of their walls. Our lungs need an internal coating of a wetting agent to make their 30 million tiny pockets (alveoli) swell uniformly when we breathe in; which leads to an explanation of why bubbles form against the wall of a beer glass, not in mid-beer.

Professor Vogel suggests two uses for his book: as the basis of a course for non-scientists in liberal studies programmes or, for biologists, as a preparation for deeper biomechanical studies and more advanced reading. *Life's Devices* will be excellent in either role. It is organized by

physical topics: dimensions and scaling principles first, then fluid mechanics, properties of materials, structures and mechanisms. All the mechanics is introduced simply, including tricky topics such as the bending of beams. There are no logarithms or trigonometrical functions, and there is even an appendix as a reminder of how equations work. No background in science is necessary to enjoy the book, only intelligence and the willingness to stop and think.

Here are a great many fascinating scientific stories, including quite a lot that I did not previously know. Too often, though, the explanations are frustratingly short. I doubt whether naïve readers will get a clear understanding of the plastron of aquatic insects, which enables them to breathe under water, from this brief, unillustrated account. I doubt whether they will appreciate the strange properties of slug slime, which enables slugs to crawl while keeping the whole area of the foot perpetually on the ground; as the slug crawls the slime under each part of its foot behaves alternately like a rubbery solid (giving the slug a purchase on the ground) and like a viscous liquid (letting it slide forward). The sparkle of the book depends on its pace, but there were times when it would better have been slowed down.

Professor Vogel is a distinguished biologist who has discovered many revealing things about the flow of water and air over animals and plants. He is also the author of a more advanced biomechanics book, *Life in Moving Fluids*, published by Willard Grant, Boston, in 1981. In an aside half way through his new book he tells us the secret of his success, which is also the book's philosophy: "A good way to make a neat discovery is to begin, not with your favorite organism, but with some physical property or phenomenon and then ask how animals might take advantage of it".

# A 140,000-year continental climate reconstruction from two European pollen records

J. Guiot, A. Pons, J. L. de Beaulieu & M. Reille

Laboratoire de Botanique historique et Palynologie, URA CNRS D1152, Faculté des Sciences et Techniques St-Jérôme, 13397 Marseille Cedex, France

The dramatic and cyclic changes that have characterized the Earth's climate throughout the Quaternary may be illustrated by developments during the last such cycle which took place over the past 140,000 years. Quantitative reconstruction of the continental climate over this period improves the correlation between marine and land records and emphasizes the role of post-temperate forested episodes at the beginning of ice-sheet formation.

IN 1971, Imbrie and Kipp<sup>1</sup> used foraminiferal data obtained from deep-sea cores in palaeoclimate reconstruction. Since then, different multivariate techniques have been used to calculate palaeoclimate parameters from fossil biological data. For continental records, pollen analysis provides the most reliable data<sup>2</sup>. Pollen is deposited as 'pollen rain' which can be characterized by a percentage representation of its components, the so-called 'pollen spectrum'. This provides a reliable reflection of regional vegetation<sup>3</sup>, and hence of regional climate. Past climates can therefore be established from the pollen content of sediments favourable to pollen preservation. Quantitative analysis of such records has until now provided palaeoclimate reconstructions for relatively short periods<sup>4,5</sup>. Here we present the results of applying an improved and simplified method<sup>6</sup>, using pollen-stratigraphic records from La Grande Pile<sup>7</sup> and Les Echets<sup>8</sup>, in eastern France, each containing a sediment sequence for the past 140,000 yr.

The results agree well with the palaeoclimate information derived from marine isotope data and emphasize the role of forested periods before glacial stadials as important episodes of ice-sheet formation. We also show that the arboreal pollen sum, often used by palaeoclimatologists as an index of continental temperature, is inadequate for this purpose.

## Methods

We assume that different climates and their corresponding vegetation types and pollen spectra, which have succeeded each other through time in the study area, can be found today in similar, analogous forms. It follows, therefore, that in order for climates to be represented that are quite different from those at the studied locality today, a very extensive study area is required to provide a wide range of analogues. We therefore first establish representative modern pollen spectra from a large area with wide variations in present-day climate and vegetation; then we define precise climate data for all the sites from which pollen spectra are obtained and identify modern spectra that are most similar to each fossil spectrum. Finally we use modern climate parameters corresponding to the best analogues to infer past climatic conditions.

There are three main problems: The climate requirements of modern plants may be different from those in the past; the range of past climatic conditions may not be fully represented today; and past and present human activity has disturbed the vegeta-

tion/climate, and hence the pollen/climate relationships in the modern pollen data set.

It is unlikely, however, that any major evolutionary changes in trees or herbs (considered here at the genus level) have occurred over the past 140,000 yr. The second problem can be overcome to an extent by using the greatest variety of modern spectra available. We try to minimize anthropogenic effects by using a method for identifying the best analogue spectra; the percentages corresponding to each taxon have been attributed a 'loading factor' which expresses the role it has played at the site throughout the period covered by the reconstruction.

## Data

The modern data, covering Europe, North Africa and Siberia, are represented by 227 spectra selected to represent a wide variety of vegetation types and climates. The 182 spectra described by Guiot<sup>6</sup> are complemented by new data from Morocco, Tunisia, Italy and Corsica, so that a total of 52 taxa could be used.

Annual temperatures and precipitation were interpolated for localities from which the spectra were collected<sup>6</sup>. Among the taxa of fossil spectra, only the 52 taxa used in the modern spectra were considered.

The Grande Pile record (47°44' N, 6°30'14" E, 330 m above sea level) is from three cores<sup>7</sup>: 'Grande Pile 1' for the Holocene (depth: 55–320 cm), 'Grande Pile XIV' for the end of the last glacial (depth: 452–1,193 cm) and 'Grande Pile X' for older periods (depth: 1,243–1,865 cm). We analysed 268 pollen spectra and as 'the miscellaneous and varying content of the pollen spectra from the section 1,170 cm–1,240 cm explains the hypothesis proposed by Gruger (1979) that they include quite a number of rebedded pollen, which deprives them of all botanical and hence climatic significance'<sup>8</sup>, we have neglected this particular section.

The Echets record (45°48'30" N, 4°55'20" E, 267 m above sea level) corresponding to the 39-m core of Les Echets G<sup>8</sup>, yielded 573 spectra (out of the 800 analysed). It was shown<sup>8</sup> that the spectra from the episodes 'Melisey I' and 'Melisey II' were contaminated by reworked arboreal pollen (AP) from earlier temperate deposits, and so for these episodes the mesic AP frequencies were limited to mean values recorded at La Grande Pile for the same periods. As the Les Echets record does not include the Holocene, data for this period are derived from Hières-sur-Amby, 30 km to the south-east but at the same elevation<sup>9</sup>.

## Results

First, we produced a time analysis of each spectra sequence to calculate how each taxon should be weighted as a climate signal. The modern ecological correlation between each taxon and climate cannot be used because of anthropogenic effects. When several well dated contemporaneous sequences are available, information that is common to all of them (mostly of a palaeobioclimatic nature) can be used<sup>6</sup>. In the present case, only the information conveyed from one level to another can be taken into account (Fig. 1a). However, such information is contaminated by noise from the local site peculiarities and (for about

the past 1,000 yr) human activity. Moreover the vegetation at any time is a function not only of the climate at that time but also of previous vegetation and climate.

Now, successive eigenvectors represent different parts of the autocorrelation (Fig. 1a), and therefore only the first eigenvector—in which climate is necessarily dominant—is retained; the others—in which noise is assumed to be dominant—are removed. Moreover, this first eigenvector maximizes autocorrelations and hence the persisting action of climate on vegetation.

The weight attributed to each taxon in the first eigenvector defines its particular role in the biological expression of the climate changes that occurred during the period concerned, and is termed the palaeobioclimatic operator (PBO). When applied to the fossil sequence, it provides a time series which can be considered as the best possible climate profile of vegetation changes.

There is a close correlation between the time series of La Grande Pile and Les Echets (Fig. 2), indicating that the operator, although derived from an autocorrelation analysis made at a single site, has a regional and therefore a climate value. This shows *a posteriori* the effective removal of any noise.

Figure 2 also shows the fluctuation of the AP sum often used by non-botanists as a palynological climate index. Note that the correlation between the AP sum at La Grande Pile and Les Echets, especially in relation to amplitude, is not as clear as that between the PBOs. In addition, comparison between the time series and the AP at each site (correlation coefficient  $r = 0.87$  at La Grande Pile and 0.85 at Les Echets) shows two main differences: the PBO increases later and decreases earlier than the AP sum; and amplitude variations in the PBO are smaller

FIG. 1 The reconstruction method may be summarized as follows: a, The transfer of the climatic information from one level to the other is estimated by the first-order multiple autocorrelation matrix  $A_1$  between the  $m$  taxa, computed on the  $n$  fossil spectra. The element  $(j, l)$  of  $A_1$  is the cross-correlation coefficient between taxon  $j$  and  $l$ :

$$r_{jl} = \frac{1}{n} \left[ \sum_{t=2}^n \frac{f_{jt} - \bar{f}_j}{Sf_j} \frac{f_{lt-1} - \bar{f}_l}{Sf_l} \right]$$

where  $f_{jt}$  represents the frequency (in percentages multiplied by 10) of taxon  $j$  in fossil spectrum  $t$ , the upper-bar represents the mean calculated across the fossil sequence and  $S$  is the standard deviation. As in principal component analysis—with a specific treatment to take into account its asymmetric character— $A_1$  is reduced to a few eigenvectors. The first eigenvector explains ~70% of the sum of squared autocorrelations (72% for La Grande Pile and 69% for Les Echets). The second eigenvector (and the succeeding ones), explaining <10% of this sum, are not retained. The weights  $w_j$  of each taxon in the first eigenvector (called PBO) are used in the second step, and also to provide the time series of the PBO (see Fig. 2):  $b_t = \sum_{j=1}^m w_j (f_{jt} - \bar{f}_j) / Sf_j$ ,  $t = 1, \dots, n$ . b, A weighted euclidian distance operator, integrating the PBO, is used to measure the similarity between fossil and modern pollen spectra and to identify the best-fit analogues for the fossil spectra:  $d_{it}^2 = \sum_{j=1}^m w_j^2 (\ln(f_{jt} + 1) - \ln(f_{ij} + 1))^2$ , where  $t$  is the index of fossil spectra,  $i$  for modern spectra, and  $w_j$  is the PBO loading affected to taxon  $j$ . This set of  $k$  most similar modern spectra is denoted  $(P_{i1}, \dots, P_{ik})$ . However, because the modern data set may not include an exact analogue for each fossil spectrum, the single best-fit modern spectrum may not be appropriate. Instead, we prefer a Monte Carlo simulation of the data, whereby  $k$  spectra are randomly extracted with replacement from the  $k$  selected spectra, and the best-fit spectrum from that group is obtained. This is repeated  $s$  times, providing  $s$  analogues from which confidence intervals are calculated. c, The estimated past climate (analogue climate  $R_t$ ) for a given analogue, indexed by  $k$ , from which the distance is  $d_{ik}$  is given by

$$^0R_t = \left( \sum_{k=1}^s C_k / d_{ik}^2 \right) / \left( \sum_{k=1}^s d_{ik}^{-2} \right)$$

The lower and upper limits of this mean estimate are

$$\begin{aligned} -R_t &= {}^0R_t - \sqrt{\sum_{k=1}^s C_k^2 / d_{ik}^2 / \sum_{k=1}^s d_{ik}^{-2}} - {}^0R_t^2 \\ +R_t &= {}^0R_t + \sqrt{\sum_{k=1}^s C_k^2 / d_{ik}^2 / \sum_{k=1}^s d_{ik}^{-2}} - {}^0R_t^2 \end{aligned}$$

The probability covering the interval  $[-R_t, +R_t]$  is defined by the proportion of modern analogous climate  $C_k$  accounted for within the range of  $s$  values.

than those in the AP during episodes of generally low forest cover.

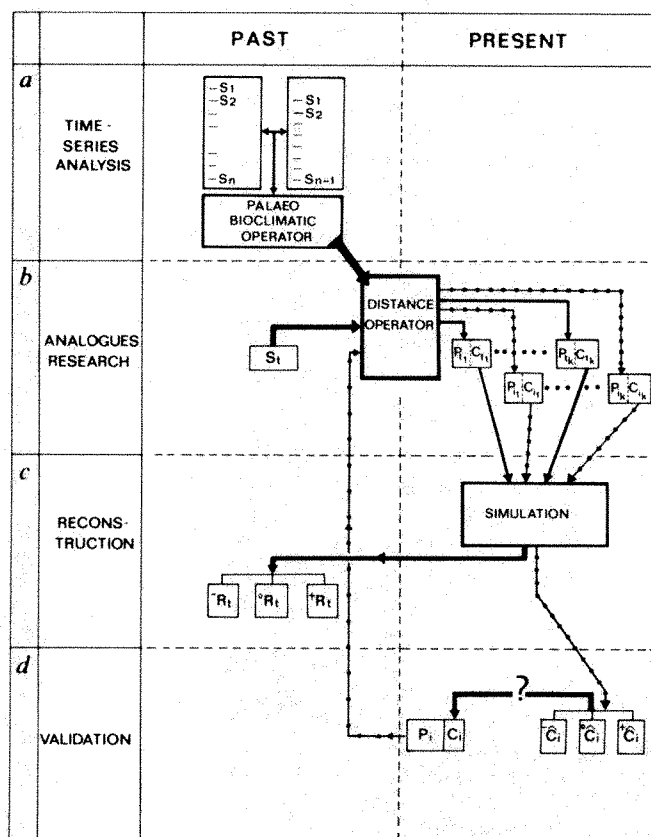

These differences arise because in the AP sum the pollen frequencies of all arboreal taxa are weighted equally whereas in the PBO the percentage of each tree taxon is weighted by its component weighting. For *Pinus* and *Betula*, this weighting may be very different from that of the other trees and close to the coefficient of non-arboreal taxa.

Figure 2 also shows that the variations in the PBO time series correspond more closely than do the AP curves to the oxygen isotope stages defined by Emiliani<sup>10</sup> and Shackleton<sup>11</sup>, represented by the stacked and smoothed record in the SPECMAP timescale<sup>12</sup>.

We next look for analogues. A weighted euclidian distance ('distance operator'), in which the PBO provides a weighting for all pollen frequencies, is used to measure the similarity between ancient and modern spectra, thus enabling us to identify the best analogues for each fossil spectrum.

We then reconstruct palaeoclimate on the basis of the climatic characteristics of the best analogues. A Monte Carlo technique (Fig. 1b) enables us to derive a climate estimate with a confidence level (Fig. 1c) of about 70%. The confidence intervals average 180 mm and 2.1 °C (Table 1). These intervals are asymmetric and slightly larger for Les Echets.

Finally, we investigate both the validity of using a PBO and our method as a whole. We reconstruct climate parameters from modern pollen spectra for which values are known (Fig. 1d). The modern spectra are dealt with in the same manner as the fossil ones, and the reconstructed climatic parameters are compared to actual data (Table 1). The estimates correlate well (0.73 on average). The confidence intervals are slightly narrower than

This interval enables one to appreciate the quality of the analogues. This simulation procedure replaces the more complicated Kalman filtering previously used<sup>6</sup>. d, We use the entire procedure described in b and c, with index  $i$  replacing index  $t$ . The modern climate triplet  $[-C_i, {}^0C_i, +C_i]$  estimated in this way is compared with actual climatic parameters  $C_i$  (see Table 1: modern data column).

TABLE 1 Validation statistics of the reconstructions

		Fossil reconstructions		Modern reconstructions	
		Precip. (mm)	T (°C)	Precip. (mm)	T (°C)
Grande Pile	ME	173	2.1	138	1.8
	*ME	183	1.8	178	1.7
	Cor	—	—	0.77	0.70
Echets	ME	156	2.2	141	1.6
	*ME	198	2.4	164	1.8
	Cor	—	—	0.75	0.71

Cor is the correlation between estimated and actual data, \*ME is the mean upper standard deviation associated to the estimates (\* $R$ –° $R$  in Fig. 1c), ME is the lower standard deviation (° $R$ – $R$  in Fig. 1c). These statistics are calculated on the fossil data and on the modern data. In this last case  $R$  must be replaced by  $C$  (see Fig. 1d).

those computed on fossil data (155 mm and 1.7 °C on average) and have a higher confidence level (>90%). Such good agreement is particularly valuable as the modern estimates are based upon coefficients calculated solely from the fossil data.

The confidence interval mean is larger than that of other reconstructions (13, for example) based upon assumptions of a gaussian distribution and homogeneity between modern and fossil data. As these assumptions are never exactly satisfied, a more appropriate method, including a simulation approach, is used. Such a method provides less optimistic but more realistic confidence intervals. Note, however, that a part of the confidence interval reflects the variability of the calibration data set, so that the cold and dry periods have larger confidence intervals than the warm and/or humid ones. This suggests that the major weakness in our reference data set is a relative lack of cold and dry analogues, which of course it is difficult to compensate for, during the present temperate period.

## Discussion

The reconstructions are obtained as a function of depth. To facilitate comparison with reconstructions from deep-sea cores,

the results are presented on a timescale (Fig. 3). The most important events before 30,000 yr BP are dated on the basis of the widely accepted isotopic chronology<sup>12</sup>, whereas <sup>14</sup>C ages<sup>8,14</sup> are used to date events after 30,000 yr BP (Fig. 2). Intermediate dates are linearly interpolated with steps of 1,000 yr.

We are aware that this procedure does not ensure the independence of our chronology with respect to that of the isotopic stratigraphy. But the succession—if not the chronology—of the climate phases shown by the pollen record is independent, and so are the reconstructed values even though the variation in time is, of course, derived from isotopic records.

The temperature and precipitation curves obtained at both sites agree well. The Holocene and the last interglacial (Eemian) appear clearly as the two warm and humid episodes which followed a complex period marked by significant rises in temperature and precipitation.

A temperature drop, which can be seen during the latter half of the Eemian and is clearly reflected in the vegetation changes, precedes a moisture maximum.

In agreement with botanical evidence, we find that a clear succession of two relatively warm and humid periods occurred after the Eemian. The first, the St-Germain I interstadial, appears as a climatically complex period because at both sites it is interrupted by relatively cold and humid short episodes and the latter half of this period is characterized by a precipitation maximum following a marked fall in temperature.

We found the two periods following the Eemian and the St-Germain I interstadial (the Melisey I and the Melisey II stadials, respectively) to be cold and dry, as expected.

For the second temperate period (the St-Germain II interstadial), we find warm and humid conditions overall, but with a tendency for low temperatures and high precipitation towards the end of the period.

The following period, the Lower Würmian Pleniglacial, was initially humid and cold, then very cold and very dry, as were the 'late Eemian-Melisey I' and the 'late St-Germain I-Melisey II' periods.

The Middle Würm then followed, a dry and cold period but far less severe than the previous stadials. At Les Echets, two

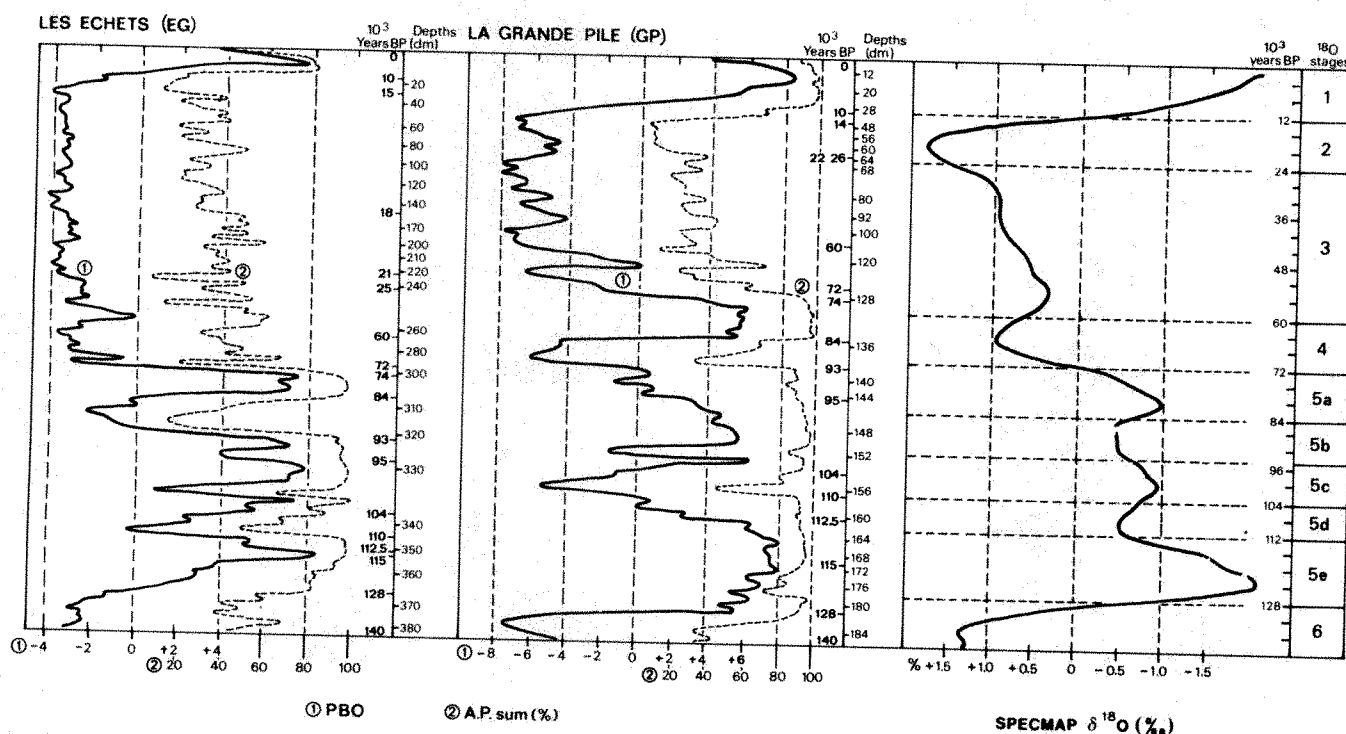

FIG. 2 The palaeobioclimatic operator time series, and the arboreal pollen (AP) sum (%) for Les Echets and La Grande Pile. These series are compared with the stacked, smoothed oxygen isotope record as a function of age using

the SPECMAP scale<sup>12</sup>. The vertical axis is linearly related to the spectra numbers. Estimated ages are given with regard to the depths.

short temperate episodes comprised a rather cool middle phase, and at La Grande Pile we found the same division into two relatively temperate episodes with an intermediate cooler one. These results support the case for a threefold division of the Middle Würm, as suggested by European Atlantic micropalaeontological data<sup>15</sup> and insolation curves<sup>16</sup>. These results, however, need to be verified because they suggest climate parameters which, throughout this period (from ~60,000 to ~30,000 yr BP), are either fluctuating (Les Echets) or poorly marked (La Grande Pile).

Because of differences in the sediments, it is difficult to compare results for the two sites for the Upper Pleniglacial. Climate, during this period, was chiefly characterized by continuous low temperatures, no such equivalent being found since the beginning of the Eemian.

Low-amplitude oscillations, mainly in relation to moisture, are recorded repeatedly, especially at Les Echets, but on the strength of botanical and sedimentological data, they are believed to result from local fluctuations rather than regional general climate variations<sup>17</sup>.

The Younger Dryas is not present in the available record of La Grande Pile and is poorly marked in the Les Echets/Hière-sur-Amby succession.

### Implications

If one agrees with Ruddiman and McIntyre<sup>18</sup> that an accumulation of continental ice implies a cold and humid continent, as opposed to a hot Atlantic Ocean between latitudes 50° and

60° N, the results presented here suggest that there were three major ice-accretion periods in Europe.

The first corresponds to the very humid and markedly cold climate of the final part of the Eemian, a prelude to the even colder and dry Melisey I stadial. The second is the end of the St-Germain I interstadial (very humid but moderately cold) which was succeeded by the cold and dry Melisey II stadial. The third ice-accretion period corresponds to the end of St-Germain II interstadial and to the beginning (markedly cold but moderately humid) of the Lower Pleniglacial, before the second very cold, dry part of this major stadial.

The main ice-accretion period, which brought about an 'inception' period<sup>11</sup> (increase of global ice above modern values), started before 110,000 yr BP, the date cited as the end of the Eemian Interglacial<sup>12</sup>. Note that the date 115,000 yr BP corresponds to minimal insolation in June, July and August at 60° N (ref. 16). A comparison of the Earth's orbital parameters at 115,000 yr BP with those of 125,000 yr BP suggests a cooling of the soil and an increase of soil moisture<sup>19</sup> in regions situated between the Mediterranean Sea and Siberia.

Isotopic and pollen analyses of an eastern Atlantic core have shown that the fall in the oxygen isotope curve based on benthic foraminifera—the beginning of the first ice-growth phase somewhere within polar latitudes—was contemporaneous with the expansion of *Carpinus* in Europe<sup>20</sup>. However, our results suggest that in Europe, the first glacial accretion began only after the *Abies* forestation episode, which followed the *Carpinus* forestation episode. This accretion, evident in foraminifera  $\delta^{18}\text{O}$

FIG. 3 Reconstruction of variations in annual total precipitation and mean temperature, expressed as deviations from the modern values (1,080 mm and 9.5 °C for La Grande Pile, 800 mm and 11 °C for Les Echets). The error

bars are computed by simulation. The vertical axis is obtained by lines interpolation from the dates indicated in Fig. 2.

data, should therefore be located in the north-west Atlantic. Changes in insolation that occurred around 115,000 yr BP and which are considered to account for this event<sup>20</sup> would then have brought about the glacial accretion on the European side of the Atlantic, with a substantial delay, as has been suggested previously<sup>28</sup>. As our chronology depends on the isotopic chronology, however, we cannot say how long this delay was.

It is generally advocated (for example, refs 14 and 20) that marine isotopic stages or sub-stages characterized by low  $\delta^{18}\text{O}$  values correspond exactly with stadial or pleniglacial continental episodes. Our reconstruction shows, during the first part of the last climatic cycle, well characterized transitions between periods of either low oceanic  $\delta^{18}\text{O}$  values (interglacial or interstadial climatic optimums) or high ones (stadials or pleniglacial). As a result, the lower limit of the continental equivalent of isotopic sub-stages 5d and 5b and of stage 4 should be situated within transition periods and not correlated exclusively and directly with the Melisey I and Melisey II stadials or the Lower Pleniglacial, so that our results are more consistent with the interpretation of the marine isotopic stratigraphy concerning the duration of substages 5d and 5b and of the stage 4 than is the previous interpretation of the continental climatic record<sup>14,20</sup>. It is

noteworthy that the transition periods, which play a major part in initiating ice-sheet formation, are forested periods. They correspond to *Picea*, *Pinus* and *Betula* forests, which mark the latter part of temperate episodes that follow the warm climate optimum; such forestation episodes are therefore often called 'post-temperate'.

The palaeobioclimatic operator appears to be the best botanical indicator of climate change, and should be preferred to the AP sum, which is unreliable, particularly for estimating palaeotemperatures. However, our reconstruction clearly suggests quite temperate conditions for the St-Germain I and St-Germain II interglacials, conditions almost similar to those of the present day, especially in relation to temperature. Such temperate phases are not recorded in the Antarctic ice cores<sup>22</sup>, in Pacific Ocean records<sup>23</sup>, or in Atlantic Ocean deep-water temperature estimates<sup>21</sup>. More surprisingly, neither are they found in records from northern Europe<sup>24-26</sup>. This might indicate a steeper thermal gradient for these periods than for today. By applying our method to pollen sequences from Padul (Andalusia)<sup>27</sup> on the one hand and to successions which contain records of these interstadials in northern Europe on the other, it should be possible to test this hypothesis. □

# The *Caenorhabditis elegans* heterochronic gene *lin-14* encodes a nuclear protein that forms a temporal developmental switch

Gary Ruvkun & John Giusto

Department of Molecular Biology, Massachusetts General Hospital and Department of Genetics, Harvard Medical School, Wellman 8, Massachusetts General Hospital, Boston, MA 02114, USA

During wild-type development, a protein product of the *Caenorhabditis elegans* heterochronic gene *lin-14* is localized to nuclei of specific somatic cells in embryos and early larvae, but is absent in late larvae and adult soma. Gain-of-function *lin-14* mutations cause the level of *lin-14* protein to remain high throughout development, resulting in developmental reiterations of early cell lineages. The normal down-regulation of the *lin-14* nuclear protein level encodes a temporal switch between early and late cell fates.

DURING the development of multicellular organisms, genes specify the proper developmental fates of cells in particular spatial domains<sup>1,2</sup> or particular cell lineages<sup>3,4</sup>; mutations in such genes transform the fates of cells into those normally found at different positions or lineages. In *C. elegans*, the temporal pattern of the cell types generated during development is explicitly controlled by heterochronic genes in an analogous manner<sup>5-7</sup>. Heterochronic mutations cause particular cells in various cell lineages and tissues to adopt fates during post-embryonic development that are normally associated with cells at earlier or later stages of development. An analysis of mutations in the heterochronic gene *lin-14* has indicated that this gene plays a central role in controlling the temporal pattern of the *C. elegans* post-embryonic cell lineage<sup>6,7</sup>. Loss-of-function *lin-14* alleles cause the precocious appearance, during early larval

stages, of cell lineages that would normally be observed in descendent cells one or two larval stages later. Conversely, gain-of-function *lin-14* alleles affect the same cell lineages but cause the opposite transformations in cell fate; thus, the early cell lineages are normal, but later cells reiterate the early cell lineages normally associated with their ancestor cells. These results indicated that relatively high *lin-14* gene activity early in development is normally reduced later in development, and that this change in *lin-14* gene activity controls a switch from early to late cell fates in all of the cells affected by *lin-14* mutations<sup>7</sup>.

The *lin-14* gene has now been cloned using a restriction fragment length polymorphism (RFLP) mapping approach<sup>8</sup>. Here we use antibodies to the *lin-14* protein to observe the cellular and subcellular location of the *lin-14* protein and the temporal regulation of its accumulation during wild-type and *lin-14* mutant development. We find that the *lin-14* protein is localized in the nucleus and that its progressive elimination during *C. elegans* development controls the normal temporal sequence of cell fates mediated by the *lin-14* gene.

### *Lin-14* protein is nuclear and temporally regulated

To overproduce the *lin-14* gene product in *Escherichia coli*, we fused the *lacZ* gene of plasmid pUR290 (ref. 9) in phase with an open reading frame from a *lin-14* cDNA clone, number 557. The *lacZ-lin-14* fusion protein was partially purified by preparative SDS gel electrophoresis and used to immunize rabbits. The resulting antisera were affinity-purified using a *lacZ-lin-14*

fusion protein column. Figure 1a shows that this antibody preparation is *lin-14*-specific.

To detect the *lin-14* protein in *C. elegans*, cell extracts were prepared from staged cultures of *C. elegans* and analysed by immunoblotting using the anti-*lin-14* antibodies. A protein of relative molecular mass ( $M_r$ ) 70,000 (70K) was detected that is most abundant in early larval stage animals but not in later stages (Fig. 1b). This 70K protein is absent in two *lin-14* null mutants (Fig. 1c), showing that it corresponds to (or, less probably, is positively regulated by) the *lin-14* gene product.

We used the affinity-purified anti-*lin-14* antibodies to detect the *lin-14* protein in whole-mount fixed specimens of wild-type *C. elegans* by indirect immunofluorescence staining, and found that the anti-*lin-14* antibodies bound antigen in specific somatic nuclei of late embryos and early larvae (Fig. 2). No immunofluorescence in somatic cells was detected in strains bearing the loss-of-function *lin-14* alleles *n536n540* and *n355n726*, which by genetic criteria behave as null alleles<sup>7</sup> (data not shown), showing that in wild-type specimens the anti-*lin-14* antibody binds the *lin-14* protein itself (or, less probably, a gene product positively regulated by *lin-14*). Because both the 70K protein detected on the immunoblots and the somatic nuclear *lin-14* staining disappear in these *lin-14* mutant strains, the somatic nuclear staining probably corresponds to this 70K *lin-14* protein.

Mutations in *lin-14* change the developmental fates of certain post-embryonic blast cells<sup>6,7</sup> (Fig. 3). By determining precisely which cells stain with the anti-*lin-14* antibody, we correlated

FIG. 1 a, Specificity of antibodies to *lin-14* on immunoblots. Lanes 1 and 3, protein extracts of IPTG-induced JM101/pUR290 cells. Lanes 2 and 4, protein extracts of IPTG-induced JM101/pUR290-cDNA557 cells. Lanes 1 and 2 were probed with sera partially purified by affinity chromatography with protein extracts from *E. coli* expressing the *lacZ-lin-14* fusion gene. The partially-purified sera recognizes both *lacZ* (lane 1) and *lacZ-lin-14* (lane 2) epitopes. Lanes 3 and 4 were probed with further purified sera from which anti-*lacZ* and anti-*E. coli* antibodies had been removed by affinity chromatography with protein extract from *E. coli* expressing *lacZ*. This sera detects only the *lacZ-lin-14* fusion protein (lane 4) (Lower  $M_r$  bands are presumably degradation products of this fusion protein that retain *lin-14* epitopes.) This sera was used for all immunological detections of *lin-14* protein in *C. elegans* protein samples and fixed specimens. The  $M_r$  of the *lacZ-lin-14* fusion protein is 175 K. b, Detection of the *lin-14* protein in extracts of wild-type *C. elegans*. The sera specific for *lin-14* was used to probe a western blot of protein samples isolated from staged *C. elegans* strains: lane 1, wild-type (N2) larval stage 1; lane 2, wild type (N2) larval stage 2. c, Lack of *lin-14* protein in two *lin-14* null mutants: lane 1, wild-type (N2) larval stage 1; lane 2, *lin-14*(*n536n540*) larval stage 1; lane 3, *lin-14*(*n355n726*) larval stage 1; lane 4, *lin-14*(*n355n726*) larval stage 3. The large protein on this blot was detected in both wild-type and *lin-14* mutants with some antibody preparations. Because it is not affected in these *lin-14* mutants, it may correspond to a cross-reacting protein.

METHODS. A cDNA library from *C. elegans* mixed-stage mRNA was constructed in  $\lambda$ gt10 using standard protocols<sup>17</sup> and screened with *lin-14* genomic clone probes. The *lacZ-lin-14* fusion gene was constructed by ligating *Sal*I-digested pUR290<sup>9</sup> DNA to *Xho*I-digested *lin-14* cDNA557 DNA using standard techniques. The antibody was generated by immunizing New Zealand White rabbits with 500  $\mu$ g of *lacZ-lin-14* fusion protein per rabbit at 20 sites. To affinity-purify the sera, total protein extracts from JM101/pUR290Sal-*Xho*I-cDNA557 and from JM101/pUR290 were each bound to derivatized beads (Affigel-10, BioRad)<sup>18</sup>. The sera was first adsorbed to the *lacZ-lin-14* affinity column, and subsequently, anti-*lacZ* and anti-*E. coli* protein antibodies were removed by exhaustive adsorption of this sera with the JM101/pUR290 protein extract affinity column. Western blots to *E. coli* extracts containing *lacZ* or *lacZ-lin-14* protein<sup>19</sup> used a 500-fold or 1,000-fold dilution of the affinity purified anti-*lin-14* antibody. Antibodies were diluted 50-fold or 100-fold for western blots to *C. elegans* extracts. Bound antibodies were detected using <sup>125</sup>I-Staphylococcus aureus protein A (New England Nuclear) at 5  $\mu$ Ci ml<sup>-1</sup> (ref. 19).

the temporal and cellular pattern of *lin-14* protein accumulation with the cell lineages affected by mutations in the *lin-14* gene and with the known developmental fates of all those cells.

The *lin-14* protein was first observed in embryos at about 7 hours after fertilization or about half-way through embryogenesis, after which time most of the embryonic cells had been generated, and cell differentiation and morphogenesis were taking place<sup>10</sup>. At this stage, the most intense staining was in intestinal and hypodermal nuclei (Fig. 2a). In later stage embryos, at about 9 hours after fertilization, additional weak neuronal staining was observed (data not shown). No lineage defects before larval stage one (L1) have been observed in *lin-14* mutant strains, and the temperature-sensitive period for *lin-14* lineage defects occurs after hatching<sup>7</sup>, indicating that the accumulation of the *lin-14* protein detected in these embryos is not yet functional.

The most intense staining that we observed at any stage was in nuclei of late embryos just before hatching, and in newly hatched L1 animals. Significantly, only nuclear staining was observed at these stages (Fig. 2b, c). In the newly hatched L1 animal, the *lin-14* protein was present in the nuclei of most of the post-embryonic blast cells; intense nuclear staining was observed in the hypodermal blast cells H1, H2, V1-V6, and T (Figs 2c and 3) and in all of the intestinal (E) cells (Fig. 2b), and weaker staining was observed in both neuroblasts Q1 and Q2, in the mesoblast M cell, and in the P cells. No staining was observed in the somatic or germ line gonadal blast cell nuclei (Z1 to Z4) at this stage.

During the L1 stage, the hypodermal blast cells H1, H2, V1-V6, T, and intestinal cells, E, all divide<sup>11</sup>. The nuclei of these progeny cells also stain with the anti-*lin-14* antibody during the mid-L1 stage. At this stage the P-cell nuclei migrate into the ventral cord and the cells divide<sup>11</sup>. The *lin-14* staining in the P-cell nuclei fades before their migration into the ventral cord but reappears later in some of their progeny cells (see below).

The intestinal (E), hypodermal (H1, H2, V1-V6, T), neuroblast Q1 and Q2, mesoblast (M), and P-cell lineages are all affected by *lin-14* mutations; loss-of-function *lin-14* mutations cause these cells to precociously express late stage patterns of cell lineages<sup>6</sup>. Wild-type blast cells accumulate the *lin-14* protein before the first cell lineage defects can be observed during the L1 stage in *lin-14* loss-of-function mutants and before the L1 temperature-sensitive period of some *lin-14* mutations<sup>7</sup>. The gonadal blast-cell lineages are not affected by *lin-14* mutations<sup>6</sup> and do not accumulate the *lin-14* protein. Thus, all post-embryonic blast cells affected by *lin-14* mutations also accumulate the *lin-14* protein at the expected time, and those post-embryonic blast cells not affected by *lin-14* mutations do not accumulate the *lin-14* protein.

The nuclei of many cells that do not divide post-embryonically also accumulate the *lin-14* protein during the L1 stage. The embryo-derived nuclei in the hypodermal syncytial cell hyp7, ABArpppapa, ABplaapppp, Cpaaaa, Cpaapa, Cpaapp, Cpapaa, all accumulate levels of the *lin-14* protein similar to those of the hypodermal blast cells (Figs 2c and 3). Terminally differentiated nuclei from embryonic body muscle also accumulate the *lin-14* protein. Nuclei of many but not all neuronal cells stain with the anti-*lin-14* antibodies. For example, the neurons BDU, ALM and CAN accumulate the *lin-14* protein but the HSN neuron does not (Fig. 2c, data not shown). All of the embryonically generated ventral-cord neurons, and some but not all of the neurons of the nerve ring and posterior ganglion accumulate the *lin-14* protein in their nuclei during the L1 stage (Fig. 2c, d, e).

These embryonic hypodermal, muscle, and neuronal cells are not affected by *lin-14* mutations but nevertheless accumulate the *lin-14* protein<sup>6</sup>. In the characterization of the *lin-14* mutants, changes in the patterns of cell division and differentiation of only blast cells, which divide post-embryonically, were scored; the effect of *lin-14* mutations on non-dividing cells was not

assessed. It is not known, therefore, whether the *lin-14* expression that we observe in these differentiated cells is in fact functional.

Late in the L1 stage, the *lin-14* protein staining of all nuclei except the neuronal nuclei is much weaker. At this stage more neurons of the nerve ring and posterior ganglion stain than at earlier stages (data not shown). Thus, in the hypodermal and intestinal cell lineages, *lin-14* protein levels peak during early L1 and fade entirely by L2. In the many neuronal cells, *lin-14* protein levels peak during mid to late L1 and fade by L2. By L2 and in subsequent larval stages, most animals showed no *lin-14* staining at all (Fig. 2f, g). The disappearance of the *lin-14* protein during the L1 stage from the nuclei of the post-embryonic blast cells correlates well with the mid to late L1 temperature-sensitive period for *lin-14* mutations<sup>7</sup>.

The temporal regulation of *lin-14* protein accumulation is displaced from this L1 peak in some cell lineages. The Pn.p cells, which do not divide until the L3 stage, do not accumulate the *lin-14* protein until that stage when they show very weak staining before the division (data not shown). This staining fades by early L4. The accumulation of the *lin-14* protein in the Pn.p cells during L3 correlates with the precocious Pn.p cell divisions, abnormal Pn.p-derived cell lineages, and resulting abnormal morphogenesis of vulval structures in *lin-14* mutants<sup>6</sup>. The temperature-sensitive period for this defect has not been determined.

In occasional L2 and L3 stage animals, weak *lin-14* protein staining in hypodermal, neuronal, and intestinal cells was observed in nuclei and cytoplasm, as if it was being slowly degraded or not efficiently transported to the nucleus. Patches of *lin-14* staining in hypodermal or intestinal nuclei was only rarely observed in very old adults (data not shown). Such sporadic accumulation of the *lin-14* protein indicates that the gene may be re-expressed under some unknown physiological conditions.

In most adults, *lin-14* immunostaining reappears only in the mature oocyte nuclei of hermaphrodites (Fig. 2h), at meiotic prophase I when the chromosomes are condensed as shown by DAPI staining (Fig. 2i). This oocyte expression of *lin-14* was not predicted by genetic analysis; no *lin-14* maternal effect has been detected (V. Ambros, personal communication). The oocyte nuclear immunofluorescence, however, remained in the *lin-14* loss-of-function mutant strains *n536n540* and *n355n726* (data not shown), indicating that these are not true null mutations for all tissues that express *lin-14*, or that the oocyte-specific antigen detected is not in fact a product of the *lin-14* gene, but rather an antigenically related gene product. The oocyte *lin-14* nuclear staining disappears after fertilization; presumably it is either degraded or greatly diluted during nuclear division. No staining is visible in early embryos.

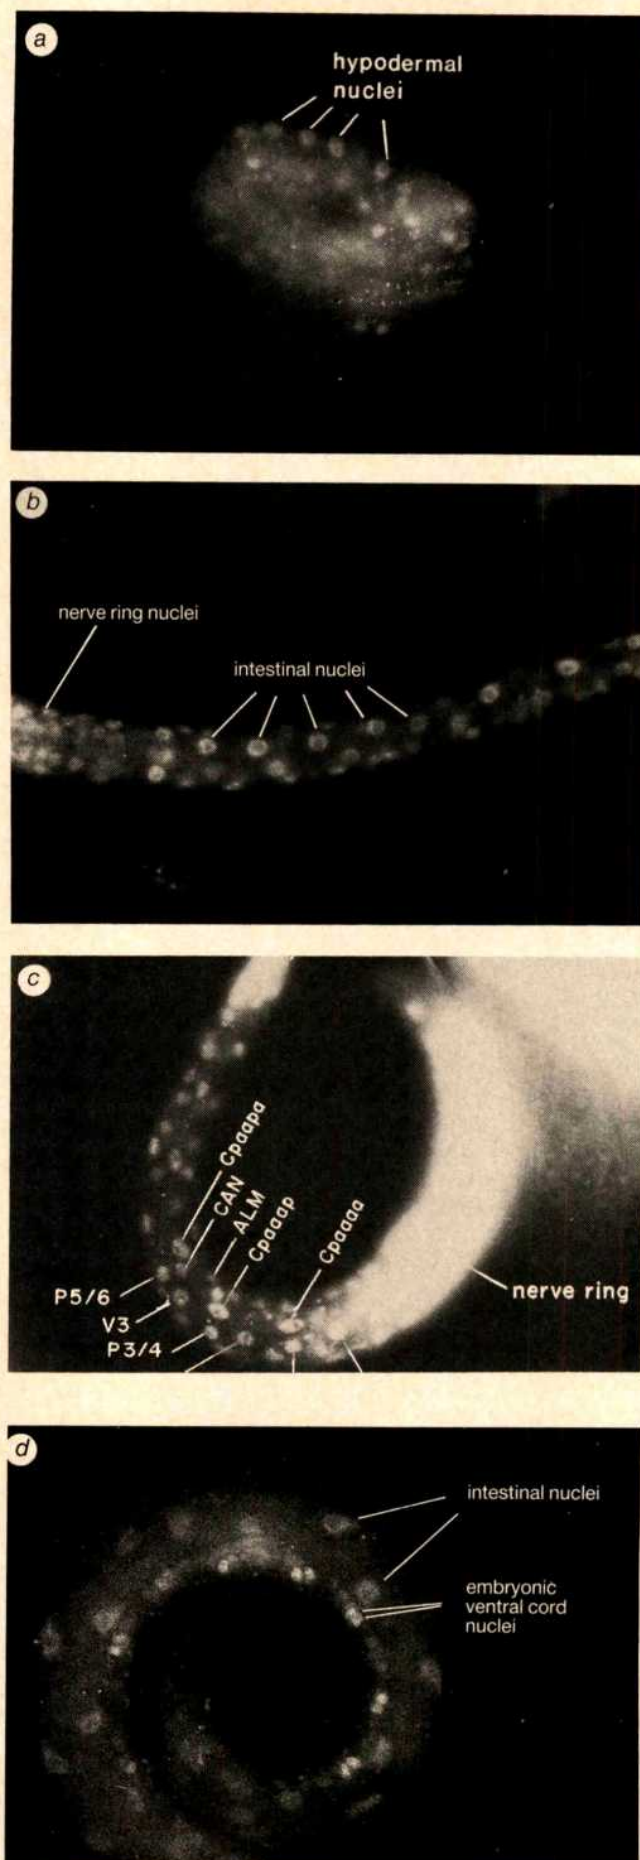

### *Lin-14* mutations

Gain-of-function *lin-14* mutations cause reiteration of early larval cell lineages at late larval and adult stages<sup>6,7</sup>. The embryonic and L1 stage staining in these mutants was equivalent to that seen in the wild-type in its intensity, nuclear localization, and cellular distribution (data not shown). Unlike the wild-type, however, these mutants showed high levels of the *lin-14* protein in many nuclei during larval stages 2, 3 and 4 and in adults (Fig. 2j, k, l). Protein staining was also observed in hypodermal, intestinal, muscle and neuronal nuclei in these late larvae and adults. All of the post-embryonic blast cells known to be affected by gain-of-function *lin-14* mutations inappropriately accumulate the *lin-14* protein at these late stages. For example, during the L3 stage, the hypodermal nuclei V4.ppp, V5.pppp and Tapapap, which in these mutants will divide like the wild-type cells V4, V5 and T, respectively<sup>6</sup>, accumulate the *lin-14* protein (Fig. 2j). The abnormal presence of the *lin-14* protein in these cells seems to change their fates into those of V4, V5 and T, respectively. Similarly, in the adult stage, the cell V4.pppp divides inappropriately in these mutants<sup>6</sup> and also accumulates

**FIG. 2** Immunodetection *in situ* of the *lin-14* protein. Specimens were fixed, made permeable and incubated with affinity-purified rabbit anti-*lin-14* antibody followed by secondary fluorescein isothiocyanate (FITC)-labelled goat anti-rabbit antibody and 4,6-diamidino-2-phenylindole (DAPI)-stained to visualize all nuclei. Immunofluorescent photographs taken with FITC filters to show *lin-14* protein staining or DAPI filters to show all nuclei are shown. All views are lateral. *a*, FITC, wild-type embryo at about 7 hours of embryogenesis. Bright nuclear *lin-14* protein staining can be seen in hypodermal nuclei. *b*, FITC, wild-type larval stage one (L1) animal with the plane of focus at the midline, showing intense *lin-14* protein staining in the large intestinal nuclei. Note that there is no nucleolar *lin-14* protein staining. Below the intestinal nuclei, the smaller nuclei of the ventral cord neurons stain with the antibody. Towards the anterior the *lin-14* protein staining nuclei of the nerve ring can be seen. *c*, FITC, wild-type early L1 animal with the plane of focus at the lateral hypoderm, showing protein staining in the lateral hypodermal blast cells V1, V2, and V3, the ventral blast cells, P1/2, P3/4, and P5/6, the neurons CAN and ALM, the embryonic hypodermal nuclei Cpaapa, Cpaap and Cpaaaa, and in the neuronal nuclei of the nerve ring. *d*, FITC, wild-type mid-larval stage-one animal with the plane of focus at the midline, posterior towards the inside of the spiral. On the inner edge of the spiral, pairs of *lin-14* protein staining nuclei from ventral cord neurons can be seen. Interspersed between these *lin-14* staining nuclei are the Pn.a-derived neural nuclei and Pn.p ventral hypodermal nuclei that do not accumulate the *lin-14* protein at this stage. The larger *lin-14* protein-staining nuclei are intestinal nuclei before the L1 division. *e*, DAPI, same animal as *d*. Note that derived in *d* many Pn.a ventral-cord neuron nuclei have not yet expressed the *lin-14* protein. *f*, FITC, Wild-type larval stage two (L2) animal with the plane of focus at lateral hypoderm. No *lin-14* staining is visible. *g*, DAPI, same animal as in *f*. View showing nuclei of the hypoderm and postdeirid neurons. A comparison of *f*, *g* with *j*, *k* shows the difference in a *lin-14* gain-of-function mutant. *h*, FITC, wild-type adult animal gonad. Shown are six mature oocyte nuclei that stain with the anti-*lin-14* antibody. Note also the lack of *lin-14* protein-staining in nuclei of somatic cells. *i*, DAPI, same animal as in *h*. The same six oocyte nuclei stained with DAPI show condensed chromosomes. *j*, FITC, Gain-of-function mutant *lin-14(n355)* larval stage three (L3) animal with the plane of focus at lateral hypoderm. Shown are hypodermal nuclei that contain the *lin-14* protein. The hypodermal nuclei contain a non-staining nucleolus. *k*, FITC, *lin-14(n536)* gain-of-function mutant larval stage three (L3) animal with the plane of focus at lateral hypoderm. *lin-14* protein staining can be seen in hypodermal nuclei (large) and neuronal nuclei (small) of the postdeirid, V5.pax. *l*, DAPI, same animal as in *k*. Note that in *k* only two of the five neuronal nuclei shown in this animal have accumulated *lin-14* protein.

**METHODS.** Indirect immunofluorescence on fixed *C. elegans* specimens: strains N2, MT355=(*n355*); MT1149=(*n536*); MT1153=(*n536n540*); GR200=(*n355n726*). About 0.1–0.5 ml of these animals were fixed in 5 ml of 2% paraformaldehyde, 80 mM KCl, 20 mM NaCl, 2 mM EGTA, 0.5 mM spermidine HCl, 0.2 mM spermine, 0.5%  $\beta$ -mercaptoethanol, 15 mM PIPES pH 7.4, to which 3 ml of *n*-heptane and 1 ml of 90% methanol, 10% 0.25 M EGTA was added<sup>20</sup>. This emulsion was shaken for 20–120 min at room temperature, then frozen in dry ice-ethanol and either immediately defrosted under warm tap water or stored at  $-70^{\circ}$  for later use. After warming, the emulsion was shaken for 60–240 min at room temperature. The fixed specimens were incubated in 5%  $\beta$ -mercaptoethanol, 1% Triton-X100, 0.1 M Tris pH 7.4 for 24 h at  $37^{\circ}$  (ref. 21). The preparation was washed extensively with PBS plus 0.5% Triton-X100 (PBST), suspended in 0.1 M Tris pH 7.4, 1 mM  $\text{CaCl}_2$ , 0.1% Triton X-100 and 1,000  $\text{U ml}^{-1}$  Collagenase VII (Sigma), and incubated at  $37^{\circ}$  for 24–48 h<sup>21</sup>. The preparation was then washed extensively with PBST and pre-incubated for a few hours at room temperature with 1% bovine serum albumin (BSA) in PBST. The fixed specimens were incubated with affinity-purified anti-*lin-14* antibody, diluted 1:10 times in PBST, 1% BSA, incubated for 24 h at room temperature, and washed for 4–24 h at room temperature with PBST, 1% BSA. The sample was then incubated at room temperature for 4–24 h with FITC-coupled goat anti-rabbit antibody (Cappel) at  $10 \mu\text{g ml}^{-1}$  that had been pre-incubated at room temperature for 4–24 h with fixed *C. elegans* specimens to remove any cross-reacting antibodies. After extensive washing in PBST, 1% BSA, the specimens were mounted on a 4% low-melting point agarose pad with  $5 \mu\text{l}$  of 1  $\mu\text{M}$  DAPI and 0.5% *n*-propyl gallate in 70% glycerol-30% 0.1 M Tris pH 9.0. Fluorescent nuclei were visualized on a Zeiss universal microscope using Zeiss filter sets 487710 (FITC) or 487705 (DAPI) and a Planapo 63 objective. Kodak TriX400 black and white film or Kodak TMY 5053 film or Fuji 400 colour film 'pushed' two f-stops in development were used for photography. No immunofluorescent staining was observed in control experiments using affinity-purified sera from pre-immunized rabbits, using the anti-*lin-14* antibodies pre-incubated with excess *lacZ-lin-14* fusion protein, or using no primary anti-*lin-14* antibody before the secondary antibody staining (data not shown). Pre-incubation of the anti-*lin-14* antibodies with excess  $\beta$ -galactosidase and *E. coli* protein extracts did not affect the immunostaining (data not shown).

temporal fates. If intermediate levels of the *lin-14* protein specify particular temporal fates, then the *lin-14* temporal switch may not be binary but in fact graded.

The generation of this temporal switch must depend both on properties of the *lin-14* gene and protein and on interactions with other gene products. The *lin-14* gain-of-function mutations disrupt this regulation. These gain-of-function mutations have been shown to delete sequences from the 3' end of the *lin-14* mRNA and must remove a negative regulatory sequence that normally mediates the down-regulation of the *lin-14* protein level during development<sup>8</sup>.

Other heterochronic genes could control developmental timing of the *C. elegans* cell lineage by participating in the generation or interpretation of the *lin-14* temporal switch. For example, a recessive mutation in the gene *lin-4* causes reiterations of early larval cell lineages equivalent to those of *lin-14* gain-of-function mutations<sup>5,6</sup>, and requires a functional *lin-14* gene for this phenotype (V. Ambros, personal communication). The *lin-4* gene product may interact with the negative regulatory site that is deleted in the gain-of-function *lin-14* mutants. Other heterochronic mutations in *lin-28*, *lin-40*, and *lin-41* cause precocious expression of late larval and adult cell lineages<sup>6</sup> (V. Ambros, personal communication). By monitoring the nature of the *lin-14* protein gradient in strains bearing mutations in these other heterochronic genes, we will be able to assess whether these genes are upstream or downstream of *lin-14* in this regulatory pathway.

Thus, the level of *lin-14* protein within nuclei decreases over time like a molecular hour glass to specify developmental time to the cell lineages affected by *lin-14* mutations. These data show that the normal temporal progression of at least some of

the cell fates observed during *C. elegans* post-embryonic development is not an emergent property of the dynamics of other developmental decisions taking place, but is under explicit control of the heterochronic genes.

The *lin-14* gene is not the only developmental clock. *Lin-14* mutant animals continue the moulting cycle, even though the fates expressed at each stage are inappropriate<sup>6</sup>. In addition, the maturation of the germ line occurs at normal times in these mutants<sup>8</sup>. These processes may be regulated by other temporal control genes.

### Pattern-formation genes and evolution

Many of the developmental control genes so far identified seem to constitute components of binary or multistate switches like *lin-14*<sup>1</sup>. It is the spatial and temporal asymmetries in the patterns of developmental control gene activity during ontogeny that make cells or sets of cells different from each other. Mutations such as the *lin-14* gain-of-function and loss-of-function mutations, which change the expression pattern of such control genes, would lead to significant morphological change and could be the main cause of the variation necessary for evolutionary change. Indeed, the *C. elegans* heterochronic mutations are analogous to the heterochronic variation between species noted in phylogenetic studies<sup>6,16</sup>. This heterochronic variation could be due to mutation in one or a few heterochronic genes like *lin-14*, rather than many mutations that incidentally change developmental timing. More generally, mutations that change the spatial, temporal or cellular asymmetries in pattern formation gene activities may be the underlying cause of the manifold forms of metazoans and may be a significant force in evolutionary change. □

### Does supernova 1987A contain a rapidly vibrating neutron star?

Q. Wang, K. Chen, T. T. Hamilton, M. Ruderman & J. Shaham

Columbia Astrophysics Laboratory, Columbia University,  
538 West 120th Street, New York, New York 10027, USA

IF the recently reported<sup>1,2</sup> 0.5-ms-period pulsed optical signal from the direction of supernova 1987A originated in a young neutron star, its interpretation as a rotational period has difficulties. The surface magnetic field would have to be much lower than expected, and the high rotation rate may rule out preferred nuclear equations of state<sup>3,4</sup>. Here we point out that a remnant radial vibration of a neutron star, excited in the supernova event, may survive for several years with about the observed (gravitationally red-shifted) period. Heavy ions at the low-density stellar surface, periodically shocked by the vibration, may efficiently produce narrow pulses of optical cyclotron radiation in a surface field of  $\sim 10^{12}$  gauss. These pulses may be modulated only slightly by a

much slower stellar rotation because of the nearly isotropic emission mechanism and smearing from the strong gravitational bending of light rays<sup>5,6</sup>. We do not attempt to explain the reported<sup>1</sup> 8-hour modulation, which may be a result of timing noise (ref. 7 and J. Katz, preprint).

Present upper bounds on the luminosity of SN1987A limit the surface magnetic field of a neutron star rotating twice a millisecond to no more than  $10^9$  gauss. Unless the field rises to  $10^{12}$  gauss in  $\sim 10^3$  yr, by the emergence of a presently buried field or from magnetothermal generation<sup>8</sup>, such a low field marks this event as very different from the Crab supernova as well as from those explosions responsible for the half-dozen other pulsar/supernova remnant associations. Moreover, the inferred rotation rate, maintained without instability, may place too severe a constraint on the equation of state of nuclear matter<sup>3,4</sup>.

Neutron-star vibrations have been discussed at some length in the literature<sup>9–11</sup>. From dimensional considerations, the fundamental radial mode period  $P$  is expected to be of the order of  $(G\rho)^{-1/2} \sim 10^{-4}$  s, with  $\rho$  the mean neutron-star density. The observed period of  $5 \times 10^{-4}$  s is close to that for a typical neutron-star model<sup>10,11</sup> (corrected for the gravitational redshift) with mass  $M \approx 1 M_\odot$  and radius  $R \approx 10^6$  cm. Non-radial and higher-

order radial modes would be damped on timescales of  $\leq 1$  yr by gravitational, neutrino and electromagnetic radiation<sup>9,10,12</sup>. A major damping source for the fundamental radial mode is the URCA neutrino-emission process<sup>13</sup>, which gives a damping time of  $\sim 10^2$  yr or longer, depending on the amplitude. However, this timescale could be reduced dramatically by several effects. (1) 'Exotic' interior states with enhanced weak interactions would magnify the radial vibration damping. These include central  $\pi$ -condensates or quark matter<sup>14,15</sup>. Confirmation of our model may rule out the presence of these in the putative neutron star produced by SN1987A, unless the neutrino emission which they can generate is suppressed by superfluid energy gaps. (2) Gravitational radiation emission would increase if there were coupling to non-radial vibrations. Such a coupling will arise when the underlying spherical symmetry is broken, for example if the neutron star is rotating. For a neutron star with a uniform density, the rotation-dependent gravitational radiation damping time is<sup>16</sup>  $\sim 2 \times 10^3 P^4$  yr, where  $P$  is the rotation period in seconds. Our model would then require a slowly rotating neutron star, with  $P \geq 0.1$  s. With such a period, a  $10^{12}$ -gauss field does not cause the neutron star spindown power to exceed the current supernova luminosity. (3) Hydrodynamic eddy diffusion and electron viscosity in the core would probably damp out an initially very large amplitude of vibration that existed when the star was still very hot.

The optical radiation is expected to originate in a region no larger than a light-travel size of 150 km. For an optical pulse luminosity of  $\sim 10^{36}$  erg s<sup>-1</sup> (18th magnitude<sup>1,2</sup> at a distance of 55 kpc) originating near a neutron-star surface, the brightness temperature  $T \geq 10^{15}$  K implies either a typical radiating-particle energy  $\geq 10^2$  GeV or coherent optical emission. X-ray measurements of the supernova luminosity<sup>17</sup> require the total power radiated by the pulsar into the supernova remnant not to exceed that emitted into the optical band by more than about  $10^3$ . Incoherent curvature radiation into the optical band is so inefficient that such an emission mechanism places a generally intolerable burden on any magnetosphere acceleration model. If electron synchrotron radiation is the source of optical emission, the local magnetic field  $B$  must certainly be much less than  $10^{10}$  G. Even with a much lower field it may be difficult to accommodate such intense optical electron synchrotron radiation. For electrons of energy  $E$  to radiate at a peak photon energy  $\epsilon$  (eV), we require

$$B \sin \alpha \leq 2 \times 10^5 \left( \frac{10 \text{ MeV}}{E} \right)^2 \epsilon \text{ gauss} \quad (1)$$

where  $\alpha$  is the electron pitch angle. A synchrotron radiation spectrum (intensity  $\sim \epsilon^{1/2}$ ) could give  $(3 \text{ eV}/\epsilon)^{1/2} \geq 10^{-3}$  of its energy in the optical band if the peak photon energy  $\epsilon \leq 10^6$  eV. For  $E \geq 10^{11}$  eV and such a value of  $\epsilon$ ,

$$B \sin \alpha \leq 2 \times 10^3 \text{ gauss} \quad (2)$$

This extreme constraint on  $B$  suggests that the radiation arises

instead from cyclotron radiation from heavy stellar surface ions,  $\text{Fe}^{Z+}$  for example. These can produce optical cyclotron radiation with a typical photon energy of

$$\epsilon \approx 3 B_{12} \frac{Z}{A} \text{ eV} \quad (3)$$

where  $B_{12}$  is the magnetic field in units of  $10^{12}$  gauss and  $A$  is the atomic number of the ion. Fully stripped energetic but nonrelativistic Fe ions can give strong cyclotron optical emission in a field  $B \approx 10^{12}$  gauss. We propose that these ions may be given the required velocities ( $v \approx 10^{10}$  cm s<sup>-1</sup> for  $10^2$ -GeV  $^{26}\text{Fe}$  ions) after the radial vibration steepens into a strong shock when it reaches the very small densities and scale heights near the stellar surface<sup>18</sup>. The shock speeds up, and ion velocity behind the shock increases as density drops sharply at the surface. In the absence of detailed numerical analysis we are unable to specify the shock details. Just after the shock the kinetic energy carried by ions will initially dominate that carried by electrons. If the local post-shock density is  $\leq 10^{-3}$  g cm<sup>-3</sup>, optical synchrotron radiation from the shocked Fe ions can compete favourably with collisional loss to the much less energetic electrons around them.

Because of the short travel time for the shock passing through the surface of the neutron star, and the short ion cyclotron lifetime ( $\leq 10^{-5}$  s), a sharp pulse may be expected within each cycle. Furthermore, because the emission is concentrated around the ion gyration frequency, the vibration-shocked surface can produce a reasonably efficient conversion of internal vibration energy to optical radiation.

The total luminosity of SN1987A sets a lower limit to the neutron-star rotation period of  $\geq 20 B_{12} L_{38}^{-1}$  ms, where  $L_{38}$  is the supernova luminosity in  $10^{38}$  erg s<sup>-1</sup>. As noted above, our model requires  $P \geq 0.1$  s. As the cyclotron emission occurs in a magnetic field that varies over the surface of the star, modulation at the stellar rotation period is expected. The amplitude of this modulation may be rather small because of the isotropic energy input from the vibration, the fairly isotropic geometry of cyclotron emission, and the strong gravitational bending of the emitted light rays<sup>5,6</sup>. However, the polarization of the emitted optical light will also vary with the stellar rotation and should be detected more easily.

Future period observations should severely test the predictions of our model; specifically the period of the neutron-star vibration (unlike that from rotation) should not increase significantly with time (although the luminosity will decrease as the vibration is damped); and the rotation period of the star should be found to be  $\geq 0.1$  s unless the vibration has been excited recently. The frequency corresponding to the peak emission in the SN1987A optical pulsar spectrum could be used to estimate the magnetic field at the surface of the neutron star (see equation (3)). The detection of X-rays from the neutron star before the vibration dies out would provide another clue as to the origin of the optical light.  $\square$

# Was the millisecond pulsar in SN1987A spun up or born spinning fast?

S. E. Woosley\* & R. A. Chevalier†

† Department of Astronomy, University of Virginia, Charlottesville, Virginia 22903, USA

**THE discovery<sup>1</sup> of an optical pulsar in SN1987A with a period of 1,968.629 Hz raises many interesting issues, chief among them being the question of how the pulsar came to acquire such a rapid rotation rate. An obvious but possibly incorrect assumption is that it was simply born that way owing to a large specific angular momentum in the iron core that collapsed. Here we argue that this millisecond pulsar, like others observed previously, has been spun up by accretion. In this case the accreted angular momentum comes from the mixed mantle and helium core of the ejecta, of which roughly  $0.1 M_{\odot}$  fell back during the first day after the explosion. This sizeable mass, and hence angular momentum, of the re-implied material is at least partly a consequence of the blue supergiant nature of the progenitor star.**

The evolution of the helium core of a massive star should, in the later stages, be decoupled from the envelope structure of the star. One expects, therefore, that the explosion of SN1987A was very similar, except in aspects related directly to the radius of its hydrogen envelope, to a typical type II supernova. There is considerable evidence to suggest that SN1987A was not particularly unusual; this evidence comes from the neutrino burst, the nucleosynthesis, the bolometric light curve and the late-time spectrum from  $\gamma$ -ray to infrared frequencies. But we have never before seen within any young supernova remnant a pulsar having such a rapid rotation rate. Could it be that this one is in a process of rapid deceleration from a (commonly occurring) initial state of high angular momentum? The limits placed on such deceleration by the discovery observation in SN1987A suggest that it is not: observations over a 7-h period (broken into half-hour intervals) revealed no more than a 0.001-Hz drift in the frequency, so that the period derivative  $\dot{P}$  is at present less than  $10^{-14}$ . The limits are in fact even more constraining, because the variations fit a sine wave with amplitude 0.0015 Hz to better than 5%, but we will adopt the less stringent number for now. Thus  $P/\dot{P}$  is considerably greater than 1,000 yr and, unless  $\dot{P}$  increases markedly in the future, the pulsar will retain its millisecond period for a long time to come. Observations of pulsars in young supernova remnants, and pulsar statistics, admittedly of objects far older than 1987A, suggest that pulsars initially have periods of 0.01–0.5 s and magnetic fields of  $\sim 10^{12}$  gauss with a small spread<sup>2–4</sup>. Such a large magnetic moment is precluded for the SN1987A pulsar because it would then be an extraordinarily bright object, much brighter than the observed brightness of roughly 100 times that of the Crab nebula pulsar in the energy band sampled<sup>5</sup>. Why, then, does the SN1987A pulsar possess such unusual properties?

We begin by noting that there is plentiful angular momentum in the cores and mantles of massive stars. The newly discovered pulsar has an angular momentum of  $\sim 10^{49}$  erg s; even without invoking differential rotation, a B0 star on the main sequence (of mass  $17 M_{\odot}$ ) with a typical rotation period of 2 days (ref. 6) and a radius of  $8 R_{\odot}$  would have angular momentum of several times  $10^{52}$  erg s. As the star evolves through the stages of nuclear burning—burning hydrogen, helium, carbon, neon, oxygen and silicon in the core and shell—convection, in particular, transports angular momentum out of the central regions of the star. The transport coefficient for this process is unknown, as is the initial distribution of angular momentum inside the star. Thus

the star might or might not end up with a collapsing core that was rotating so fast as to be near breakup.

The iron core that collapses experiences more stages of convection than any other part of the star. Each time the core contracts to ignite a new fuel, these convective episodes sweep angular momentum out, usually to a region just inside the Chandrasekhar mass. Convective shells, especially oxygen-burning, may be efficient in carrying the angular momentum out still farther. Thus a relatively slowly rotating core of  $1.5 M_{\odot}$  could plausibly collapse within a surrounding mantle endowed with considerable angular momentum, especially near its inner edge. A very approximate estimate for the angular momentum contained within the  $2.0 M_{\odot}$  of the core at central carbon ignition is  $2 \times 10^{50}$  erg s (Fig. 7 of ref. 7; see also ref. 8). Later stages of convective carbon, neon, oxygen and silicon burning would transport angular momentum but would leave a substantial residual in the  $\sim 1 M_{\odot}$  of material outside the iron core. About  $0.1 M_{\odot}$  of this material could easily contain an angular momentum of  $10^{49}$  erg s.

Moreover, SN1987A has clearly demonstrated the importance of mixing. The composition of the heavy-element core has been stirred by Rayleigh–Taylor instabilities, some in the reverse shock as the helium core runs into its own hydrogen envelope, some powered by the decay of radioactive  $^{56}\text{Ni}$  and  $^{56}\text{Co}$ , and possibly some caused by the unknown explosion mechanism itself (which may involve neutrinos creating a sizeable bubble of radiation inside the star<sup>9</sup>). In this mixing process, angular momentum as well as composition will inevitably be distributed, and in particular some material with high specific angular momentum will be mixed inwards<sup>10</sup>.

Once the explosion has occurred and the shock wave is propagating outwards, a substantial amount of matter may fall back onto the neutron star during the reverse shock into the mantle, caused by the helium core running into the massive hydrogen envelope<sup>10–13</sup>. Before the discovery of the pulsar, it was estimated that  $\sim 0.1 M_{\odot}$  of material had fallen back in SN1987A, although the errors of the calculation permit the actual value to be several times greater (or smaller). Thus sufficient angular momentum could fall back to spin up the neutron star.

The accretion is sensitive to the density of material in the vicinity of the neutron star, which decreases with time roughly as  $t^{-3}$  until the reverse shock arrives and slows the expansion. For a red supergiant, a more typical supernova precursor, it takes ten times longer for the helium core to encounter a mass equal to its own, so the reverse shock is delayed. Meanwhile the density decreases and less matter accretes. It is estimated<sup>10</sup> that 100 times less matter would accrete in the explosion of a red supergiant than in SN1987A. This could explain why neutron stars born in more typical type II supernovae end up rotating more slowly. If so, the rapidly spinning pulsar may be yet another special attribute of the relatively small radius of the anomalously blue supergiant progenitor.

The limit to the degree of spin-up, however, lies not just in the supply of angular momentum but in the efficiency with which it can be added. We assume that material can accrete with a tangential velocity no greater than the Keplerian orbit speed. General relativity modifies the newtonian value<sup>10</sup> because there are no stable orbits inside 3 Schwarzschild radii,  $R_s$  (for a rapidly rotating neutron star this value is reduced to 1.75–2.2  $R_s$  (ref. 14)). The angular momentum delivered to a (non-rotating) neutron star of mass  $1.5 M_{\odot}$  is  $4.6 \times 10^{48}$  erg s per  $0.1 M_{\odot}$  accreted ( $3^{1/2} R_s c$  per g; (ref. 14)). This means that roughly  $0.2 M_{\odot}$  needs to have fallen back onto the neutron star. If the neutron star were still rotating highly differentially, with the crust moving much faster than the superfluid central core (which contains most of the moment of inertia), the required mass could be much less. Recent studies<sup>25</sup> suggest, however, that the crust and core are efficiently coupled and that the timescale for communicating angular momentum is quite short, certainly less

than a year. If the timescale were one year,  $\dot{P}$  would be much greater than the limit given above. For now we adopt the more restrictive assumption of rigid rotation.

The (baryon) mass of the neutron star inferred from the neutrino burst is in the range  $1.2\text{--}1.7 M_{\odot}$  (ref. 16) with most probable values near the middle of the range; clearly, an addition of  $0.2 M_{\odot}$  to a  $1.5 M_{\odot}$  neutron star would give a mass of  $1.7 M_{\odot}$ . The maximum mass of a hypothetical neutron star<sup>17,18</sup> having equation of state 'F' (which is relatively 'soft') and a period of 0.5 ms is  $1.87 M_{\odot}$  (for which the moment of inertia is  $1.16 \times 10^{49}$  erg s). Without rotation, a neutron star of mass  $1.7 M_{\odot}$  would be unstable to collapse for such an equation of state. Although the gravitational masses (roughly 10% less than the baryon mass) of neutron stars in our Galaxy may be less than  $1.5 M_{\odot}$  (ref. 19), the new pulsar probably needs to be more massive than this in order to rotate as rapidly as it does<sup>17,18</sup>. Accretion, as described here, would produce the required mass increase naturally.

Most of this mass addition would have occurred early on, with a maximum rate occurring soon after the reverse shock reached the core (that is, 2 hours after the explosion<sup>20</sup>). Most of the accretion energy would have been expelled in the form of neutrinos<sup>21</sup>. And additional energy radiated would be negligible compared to the supernova energy on day 1. Although our model has a large accretion rate in the early phases, this can be reduced by the escape of radiation from the vicinity of the neutron star after about 7 months (ref. 10). The present accretion rate onto the pulsar must be very small so as to accommodate the known bolometric luminosity of  $3 \times 10^{38}$  erg s (R. Catchpole, personal communication). All radiation with energy below 10 keV would still be effectively converted to light in the optical and infrared bands<sup>22</sup>, so the present accretion rate is below about  $10^{-8} M_{\odot} \text{ yr}^{-1}$ . For such a small  $\dot{M}$  (and  $\dot{P}$ ), the pulsar is in no immediate danger of becoming a black hole. If added at the Keplerian velocity, accretion at a rate of  $10^{-8} M_{\odot} \text{ yr}^{-1}$  would contribute angular momentum to the neutron star at a rate several orders of magnitude below the limit inferred from  $\dot{P}$  in the observations.

The mass addition could also have the interesting effect of reducing the surface magnetic field strength, as a result of an initially very high accretion rate of material with a disordered magnetic moment, which could bury the magnetic field of the accreting neutron star. A field of  $10^{12}$  gauss would be overwhelmed by an accretion rate of only  $0.002 M_{\odot}$  per day, which is considerably less than the rate expected. Alternatively, convection and nuclear activity in the accreted material may have reduced the surface field<sup>23</sup>. An interesting consequence of the model proposed above is that the magnetic dipole field of the core, initially buried by accretion, may eventually emerge, leading to a brightening of the pulsar and a more rapid spin-down.

There are surprisingly few major observational differences between a pulsar born rotating fast and one spun up during the first day of its life. The latter would certainly have a greater mass, but not so great as to be incompatible with the proposed nuclear equation of state. To distinguish between the two may require a consideration of all observations and models of the supernova, paying special attention to the explosion mechanism. Our model offers the advantage of explaining why this pulsar is unusual and of coupling this peculiarity to the structure of the progenitor star Sk-69 202. Given that a plausible explanation for the blue nature of that star is, at least in part, a manifestation of the low metallicity of the Large Magellanic Cloud<sup>20,24</sup>, one implication of the model is that similar millisecond pulsars may have been created in other metal-deficient regions. However, there are other factors besides metallicity that are involved in the evolution of a blue supergiant progenitor<sup>24</sup>. These include the mass of the star ( $15 \leq M/M_{\odot} \leq 22$ ), the efficiency of semi-convection (which is small), and the amount of mass loss (also small). It is unlikely that all pulsars in the LMC would be born

as millisecond pulsars, but it is possible that some could. Pulsar 0540-69, for example, which is also in the LMC and within a remnant of estimated age 800 yr (ref. 25), has a 'normal' period of 50 ms and probably also a strong magnetic field.

## Geminga and the search for optical counterparts of $\gamma$ -ray-burst sources

Fulvio Melia

Department of Physics and Astronomy, Northwestern University, Evanston, Illinois 60208, USA

THE nature of gamma-ray-burst (GRB) sources has remained a mystery, in part because of the lack of any optical identification. Recently, deep CCD photometry has identified the optical counterpart G' to the  $\gamma$ -ray source Geminga, whose location on a colour-magnitude diagram is unique<sup>1</sup>. Although the X-rays from G' are probably due to thermal emission from the neutron star, the implied column density ( $\geq 5 \times 10^{20}$ ) is inconsistent with the distance ( $D < 100$  pc) required to fit the optical flux to the same spectral component. Here I show that the optical emission could be due instead to a cold accretion disk with accretion rate  $\dot{M} \approx 10^{11} \text{ g s}^{-1}$ . This has promising implications for the search for the optical counterparts to GRB sources whose basic physical parameters may resemble those of radio pulsars and related objects such as Geminga. I argue that a similar search in the field of a GRB location should produce candidates similar to G' if  $20 \text{ pc} \leq D_{\text{GRB}} \leq 500 \text{ pc}$ , as predicted by the disk-reprocessing model for the associated optical transients. This possibility is discussed in the light of the fact that the first optical counterpart to a GRB source may already have been found, which, if it is confirmed, may be used to test the accretion-disk model.

The confirmed optical identification of 1E0630+178 with a 25-mag blue object (G'') makes it very likely that this X-ray source is an isolated neutron star and strongly suggests that it is the counterpart to the high-energy  $\gamma$ -ray source Geminga<sup>1</sup>. The detection of thermal emission from a neutron star is not new. The discovery of G' is significant, however, because of its

similarity to Vela-type pulsars and because of the possibilities implied in respect of the search for the quiescent counterparts of GRB sources, which may themselves be isolated, magnetized neutron stars.

Although the basic mechanism for producing GRBs is not yet well understood, support for the neutron-star model is extensive<sup>2</sup> and has been augmented by the confirmation of low-energy features (interpreted as cyclotron resonances) in some GRB spectra<sup>3-8</sup>. It is not surprising, therefore, that GRB sources have sometimes been associated with extinct pulsars<sup>9-11</sup>. The similarities between the two include the following. (1) Both seem to be isolated neutron stars<sup>12-14</sup>. (2) At least some of the GRB sources, like pulsars, are highly magnetized (with surface magnetic fields  $\geq 10^{12}$  gauss (refs 5, 6)). (3) Several pulsars (including PSR0531+25 and 0833-45) emit detectable fluxes of  $\gamma$ -rays up to energies in excess of  $2 \times 10^3$  MeV (ref. 15), with a flux density that falls off as a power law characterized by an index  $\alpha \approx -1$ . Significantly, the Gamma-Ray Spectrometer on the Solar Maximum Mission satellite has discovered that emission of  $>1$  MeV (with  $-2 \leq \alpha \leq 0$ ) is a common component of GRBs, and that in many cases it actually dominates the emitted power<sup>6,16</sup>. (We note, however, that GRB spectra below  $\sim 1$  MeV are not always similar to those of rotation-powered pulsars.) (4) There is some evidence that GRB sources may have periods<sup>17</sup> similar to those of pulsars<sup>18</sup>. However, the pulsar period distribution peaks around  $\sim 0.5$  s (and extends down to 1.6 ms in the case of PSR1937+214), whereas the periods in GRBs (if confirmed) fall in the range  $\sim 1$ -10 s. Although this distinction may be simply a selection effect (that is, faint, slow pulsars are undetectable at large distances, and GRB periods  $\ll 1$  s may be 'hidden' by the intrinsic rapid variability of the burst flux), it might also be an indication that GRB sources are indeed extinct pulsars and that the transition from one population to the next occurs when the spin period of the neutron star exceeds  $\sim 2$  s (ref. 11). On the other hand, it might simply indicate that although the two types of systems have similar properties, they form by different processes which lead naturally to different period distributions<sup>19</sup>.

Is it possible then, in view of this close analogy between Geminga-type sources and GRB sources, to predict the observable characteristics of the optical counterparts to the latter? Before addressing this question, let us consider the status of

Geminga and its identification with G'. Deep CCD photometry<sup>1,20</sup> at the Einstein Observatory shows that the star in question is by far the bluest object in the field of the Einstein error circle of the X-ray source 1E0630+178 (Fig. 1). Even though deep optical searches reaching beyond 25 mag reveal many objects, a source such as G', with a large and significant departure from colours expected and observed from the field stars of similar magnitude, occupies a distinct, outlying position on a colour-magnitude diagram. Quantitative photometry and reanalysis of the Einstein data led Halpern and Tytler<sup>1</sup> to conclude that the optical and X-ray emission together are consistent with a single-temperature black-body spectrum of temperature  $T = (4.3 \pm 1.7) \times 10^5$  K, although the X-ray data alone are best fitted by  $T = 1.1 \times 10^6$  K. This is an important distinction because the lower temperature implies a distance  $D < 100$  pc, whereas the higher temperature requires both that  $D < 2$  kpc and that the optical emission must have another source. In view of the fact that the column density  $N_H$  corresponding to the single-temperature fit is at least  $5 \times 10^{20}$  (which is much larger than the measured values within 100 pc of the Sun in this direction), a line of sight with this value of  $N_H$  would more probably extend to  $\sim 500$  pc. There is thus an inherent difficulty with the single-temperature model. (One should keep in mind, however, that the surface composition of isolated neutron stars is poorly known and a black-body fit to the X-ray spectrum may not be adequate<sup>21</sup>.) A second objection to the smaller distance implied by the single-temperature fit is the correspondingly small displacement of the source away from our galactic plane ( $\leq 7$  pc), which is statistically unlikely<sup>1</sup>.

The optical emission from G' may be due to a distinct (perhaps synchrotron<sup>1</sup>) component. I propose that at least part of this optical flux may be emitted by a cold accretion disk surrounding the neutron star. Systems such as this have already been considered in disk models for pulsar action<sup>22</sup>, and as possible  $\gamma$ -ray-burst sources<sup>10,23,24</sup>. In addition, there is some evidence that these disks are necessary to account for the optical transients associated with some GRBs<sup>14,25,26</sup>.

To explore this possibility, I have assumed a model in which the optical and X-ray fluxes are due to a thermal, isotropically radiating neutron star<sup>27</sup> with a temperature  $T_0 = 1.1 \times 10^6$  K, mass  $M = 1.4 M_\odot$  and radius  $R = 10$  km, and a cold disk whose emission may be treated as a sum of black bodies<sup>6,14</sup>. The maximum disk temperature,  $T_{\max} = [3GM/65\pi\sigma R_{\max}^3]^{1/4} = 1.22 \times 10^5 (M/1.4 M_\odot)^{1/4} (R/10 \text{ km})^{-3/4} \eta^{-3/4}$  K, is attained at the equatorial radius  $R_{\max} = (49/36)R_{\text{in}}$ , where  $R_{\text{in}} = \eta R$  defines the inner edge of the disk and  $\eta$  ( $\sim 3$  for the systems considered here<sup>6,14</sup>) is a parameter characterizing the Alfvén radius. Thus, accretion disks driven by ordinary degenerate electron viscosity have temperatures (corresponding to accretion rates  $\dot{M} \approx 10^{10} \text{ g s}^{-1}$ ) that are too low for them to be detected from X-ray emission, but that permit them to contribute significantly to the optical flux because of their large emitting surface area.

Figure 1 shows the magnitude and colour expected of G', together with the published data<sup>1</sup>. Because  $\eta \approx 3$ , only the parameter  $\dot{M}$  can influence the result significantly. (The inclination angle  $i$  of the disk to the line of sight enters only through a factor of  $\cos i$ , which I will assume to be 0.7 in all the calculations.) For a fixed  $\dot{M}$ , the range in the  $g$  magnitude reflects the uncertainty in the source distance  $D$ , whereas the extent in  $g-r$  on the colour-magnitude diagram corresponds to the unknown degree of reddening  $A_g$ . (The value  $A_g = 1.7$  is the maximum observed in this direction<sup>1</sup>.) Once the neutron-star temperature and distance ( $\sim 500$  pc) are fixed by the X-ray data, the optical data, which provide a colour and magnitude, can be fitted with just one essential parameter ( $\dot{M}$ ). The diamond-shaped region shown in Fig. 1 corresponds to an accretion rate  $\dot{M} = 10^{11} \text{ g s}^{-1}$ . Note that, for these parameter values, a distance  $D \approx 500$  pc would imply an amount of reddening corresponding to  $A_g \sim 0.3$ -0.4.

FIG. 1 Colour-magnitude diagram for the stars in the field of the Einstein error circle for the X-ray source 1E0630+178 (Geminga). At a distance  $300 \text{ pc} \leq D \leq 1 \text{ kpc}$ , thermal emission from the surface of a neutron star with a temperature ( $\sim 1.1 \times 10^6$  K) fitted to the X-ray data cannot account for the optical flux. The region enclosed by the diamond corresponds to the magnitude and colour of an accretion disk with accretion rate  $\dot{M} \approx 10^{11} \text{ g s}^{-1}$ .  $A_g$  is the reddening in the direction of this source. (Data are taken from ref. 1.)

The success of this fit is promising in so far as GRB sources are concerned because they may contain cold accretion disks<sup>10,14,23-26</sup>. Application of the disk-reprocessing model to the optical transients associated with GRBs<sup>14,19</sup> predicts distances in the range  $\sim 20$ –500 pc for the four known optical-transient (OT) GRB sources, not unlike that of Geminga. Of these, the OT1928/GRB1978 object<sup>28</sup> is predicted by this model to be the closest, with  $20 \text{ pc} \leq D \leq 150 \text{ pc}$ . Perhaps not coincidentally, this also happens to be the GRB source for which the best attempts have been made to search for a quiescent optical counterpart<sup>29,30</sup>.

The colour-magnitude data for all those sources in the field of the OT1928 error box for which colour information is available<sup>30</sup> are shown in Fig. 2. Although these sources are much fewer in number than those in Fig. 1, the similarity of the two plots is nonetheless apparent. Also shown in this figure is the range in  $B$  and  $B-V$  predicted on the basis of the simple neutron-star-plus-disk model described above. In this case, the amount of reddening is expected to be very small ( $A_B \approx 0$ ) because the source is relatively close. The allowed range in  $B$  and  $B-V$  is instead due to the uncertainty in the accretion rate and distance. As before, standard parameter values were chosen for the neutron star, which was also assumed to have a surface temperature  $T_0 \approx 10^5 \text{ K}$ , consistent with the most constraining X-ray observations currently available for this source<sup>31</sup>.

As was the case for  $G''$ , there is no question that the source DD is unique among the objects detected in the field of the OT1928 error box: main-sequence stars with  $B \geq 25$  and  $B-V \leq 0$  would have to be early types with  $D \approx 10 \text{ kpc}$ , which is unlikely given that the galactic latitude of this field is  $\sim -84^\circ$ , and active galactic nuclei with this colour are typically much brighter ( $V < 20$ ). CC has a magnitude similar to DD, but its colour and magnitude together are consistent with a normal late-K-type main-sequence star. The proximity of DD to the predicted range of  $B$  and  $B-V$  suggests that, if this object is indeed an isolated neutron star surrounded by an accretion disk, then  $10^7 \text{ g s}^{-1} \leq \dot{M} \leq 10^9 \text{ g s}^{-1}$  and  $D \approx 100 \text{ pc}$ , as predicted by the disk-reprocessing model<sup>14</sup>. Thus, in conjunction with deep CCD photometry to identify more precisely the magnitude and colour of DD, confirmation of candidate DD as the burst source would strongly support this model, whereas ruling it out would argue against it. If this model is correct and the connection between GRB sources and pulsars is borne out by further observational

testing, the longer periods (if confirmed), the lower neutron-star surface temperatures and the apparently lower accretion rates in GRB sources argue either for an older (perhaps extinct) branch of the pulsar population or for two distinct populations differing only in the scale of the physical parameters characterizing their constituents.

Obtaining CCD photometry to a limiting magnitude ( $5\sigma$  detection threshold) of 26 in  $B$ ,  $V$  and  $R$  band-passes is feasible in principle at prime focus on a 4-m telescope. Although the historical OTs (found on archival photographs) and the modern-day GRBs are separated by as much as 40 years, the sources will not have shifted position by more than  $\sim 9''$  for a transverse velocity of  $\leq 50 \text{ km s}^{-1}$  at a distance of 200 pc. Because of its unique colour, any GRB source within the CCD's  $\sim 4' \times 4'$  field of view centred on the OT location should stand out clearly in a colour-magnitude diagram. Such an effort should at least be carried out for the source DD, which is arguably our strongest candidate for an optical counterpart to a GRB source.  $\square$

## Evidence from Voyager II photometry for early resurfacing of Umbriel

Paul Helfenstein, Peter C. Thomas & Joseph Veverka

Center for Radiophysics and Space Research, Cornell University, Ithaca, New York 14853-6801, USA

THE uranian satellite Umbriel's dark, heavily cratered surface is remarkable for its apparent uniformity in Voyager II images<sup>1</sup>. Its most conspicuous geological feature is a comparatively high-albedo, annulus-shaped deposit which covers the floor of the 40-km diameter crater Wunda<sup>1</sup>. Here we present new Voyager II albedo maps of Umbriel which reveal that its surface is subdivided into low-contrast, crudely polygonal areas ranging in size from tens to hundreds of kilometres (Fig. 1). The largest polygons are elongate with systematically trending northeast-southwest boundaries. Some of the polygonal areas form topographic depressions several

FIG. 2 Colour-magnitude diagram for the stars in the field of the 1928 optical transient, which seems to be associated with the 1978 November 19  $\gamma$ -ray burst. As is the case for  $G''$ , the position of source DD is unique. Its proximity to the region of  $B$  versus  $B-V$  predicted by the 'single-neutron-star plus cold-disk' model makes it a very strong candidate for the optical counterpart to this GRB source. (Data are taken from ref. 30.)

FIG. 1 *a*, Voyager image FDS 26825.51 after shading correction and contrast enhancement. Phase angle is  $31^\circ$  and resolution is 16 km per line pair. *b*, Highest-resolution Voyager image (FDS 26840.04), processed as in *a*. Phase angle is  $56^\circ$  and resolution is 8 km per line pair. *c*, *d*, Sketch maps showing locations of features identified in our albedo map (Fig. 2*a*) as they would appear in images at left. Arrows identify the locations of parallel topographic grooves. The brightest features are bright craters. Irregularly shaped dark areas are prominent dark polygonal terrains.

kilometres in depth. We suggest that this newly discovered global albedo pattern is a relic of the early tectonic disruption of Umbriel's surface.

We have prepared a new, photometrically accurate map of Umbriel's surface which reveals a low-contrast global albedo pattern not recognized previously (Fig. 2*a*). This map is a composite constructed by first correcting the brightnesses in each Voyager image to compensate for differences in viewing and illumination geometry (Fig. 1*a*, *b*), and then projecting the image into standard polar stereographic coordinates. The digital map in Fig. 2*a* represents a mosaic of four such projected images (Voyager FDS 26788.15, 26797.22, 26825.51, 26840.04).

To perform shading corrections to each image, we applied the analytical equation of Hapke<sup>2-4</sup>, which describes the variation of surface brightness of rough particulate surfaces with changing photometric geometry. For any given surface element, photometric geometry is specified by three angles: incidence angle,  $i$ , emission angle,  $\epsilon$ , and phase angle,  $\alpha$  (the angle subtended between two vectors pointing from the surface to the Sun and to the observer). Hapke's equation requires five model parameters whose values we determined from observations of Umbriel's changing brightness during different phases of the Voyager II encounter. Two of the parameters,  $\bar{\omega}_0$ , the average particle single-scattering albedo, and  $g$ , the asymmetry factor in the Henyey-Greenstein<sup>5</sup> particle-phase function, are closely related to the composition and mechanical structure of soil particles. The opposition effect (a surge in brightness observed in particulate surfaces at low illumination and small viewing angles) is described by two parameters:  $h$ , which relates the angular width of the surge to the state of compaction of surface particles, and  $B_0$ , which describes the amplitude of the opposition surge. Macroscopic surface roughness is described by Hapke's  $\bar{\Theta}$  parameter, the average slope angle of sub-resolution-scale topographic relief.

Preliminary global-average values of these parameters have been determined from 'clear-filter' ( $\sim 0.48 \mu\text{m}$ ) observations by Voyager of Umbriel's integrated-disk brightness<sup>5</sup>. That study

provides the best available estimates of opposition surge parameters ( $B_0 = 2.01$ ,  $h = 0.06$ ), but improved estimates of  $\bar{\omega}_0$ ,  $g$  and especially  $\bar{\Theta}$  can be obtained on the basis of Umbriel's disk-resolved photometric behaviour. Accordingly, we have collected disk-resolved measurements of Umbriel's brightness from five clear-filter Voyager images (FDS 26788.15, 26797.22, 26825.51, 26840.04, 26904.04) covering phase angles from  $10.4^\circ$  to  $142.9^\circ$  and averaged in bins of  $5^\circ$  of photometric latitude and longitude over each visible disk (excluding the few visible bright craters). Optimal values of  $\bar{\omega}_0 = 0.35$ ,  $g = -0.18$  and  $\bar{\Theta} = 26^\circ$  were then determined by fitting Hapke's equation to these data using a nonlinear least-squares algorithm<sup>6</sup>.

Figure 1*a* and *b* shows the highest-resolution images of Umbriel after performing the shading correction and after contrast stretching to enhance details. Quasi-polygonal discontinuities between coherent regions of lower and higher albedo can be identified clearly in Fig. 1*a* and, less easily, in Fig. 1*b* (for which resolved topographic texture more strongly obscures albedo markings). The fact that these features become more distinct with decreasing phase angle suggests that they are indeed albedo markings rather than shadows cast by topography. Some of the discontinuities define closed, approximately polygonal areas (Fig. 1*c*, *d*), ranging from less than 50 km to greater than 600 km in size. In many cases, albedo contrast between adjacent polygonal areas is too variable along the boundaries to allow clear definition of complete polygons.

In Table 1 we list normal albedos (the reflectance at normal incidence and emission angles) of selected features on Umbriel. The average normal albedo of Umbriel is 0.21. The brightest feature on the satellite, the bright annulus crater, has an albedo of 0.49 and a contrast of 40%. In comparison, the apparent albedo contrast of probable bright-crater ejecta is only about 5%. The photometric contrast between the darkest polygons and typical surrounding regions is only 2.4%.

The composite albedo map can be used to examine the distribution of dark polygons over Umbriel's visible surface. On scales of less than about 100 km, polygons seem to have random orientations. However, sub-global-scale polygons at  $25^\circ$  S,  $300^\circ$  E and  $73^\circ$  S,  $270^\circ$  E are elongated, with nearly parallel northeast-southwest-trending lengthwise boundaries. A pattern of parallel topographic grooves (shown by arrows in Fig. 1*c* and *d*) cross-cuts the long boundary of one of these polygons at large angles.

At the highest resolution possible for Voyager (11 km per line pair), it is difficult to identify visually any possible topographic boundaries that may be separating polygons. Thomas<sup>7</sup>, however, has recently derived accurate elevation profiles along the limb of Voyager image FDS 26840.04, which projects into our albedo map along the arrow labelled A-A' in Fig. 2*a*. In Fig. 2*b* and *c*, we compare the limb elevation profile of Thomas with the corresponding normal albedos along the length of the limb projection in Fig. 2*a*. A close, but not perfect, correspondence between albedo and topography is evident: areas of lower albedo are topographically lower, and higher albedos are associated with topographic highs. We stress that the topography shown

TABLE 1 Clear-filter normal albedos for selected features on Umbriel

Feature	Location	Normal albedo
Global average		$0.21 \pm 0.02$
Darker polygons	$19^\circ$ S $310^\circ$ E	$0.202 \pm 0.011$
	$65^\circ$ S $7^\circ$ E	$0.191 \pm 0.004$
Brighter polygons	$83^\circ$ S $135^\circ$ E	$0.204 \pm 0.002$
	$83^\circ$ S $98^\circ$ E	$0.209 \pm 0.002$
	$56^\circ$ S $257^\circ$ E	$0.202 \pm 0.002$
Bright craters	$82^\circ$ S $270^\circ$ E	$0.232 \pm 0.007$
	$42^\circ$ S $192^\circ$ E	$0.226 \pm 0.004$
Bright annulus	$5^\circ$ S $273^\circ$ E	$0.491 \pm 0.051$

was determined from limb geometry, that is, by a method totally independent of photometry (which is to say, of albedo).

There is no obvious stratigraphic relationship between darker and brighter polygons; but their existence, along with systematic patterns of global orientation and the nature of the topography, is consistent with the interpretation that they are relics of tectonic breakup and resurfacing of Umbriel. The tendency for lowest-albedo materials to occur in low-lying terrains is consistent with an internally driven resurfacing event involving darker materials. Such darker materials are known to have been extruded on other uranian satellites, that is, certainly on Miranda and probably on Oberon.

The apparent muting of topographic boundaries between polygons by accumulated impact craters suggests that the proposed resurfacing occurred very early in Umbriel's geological history. Indeed, Strom<sup>8</sup> has suggested, on the basis of cratering statistics, that Umbriel was resurfaced earlier than other uranian satellites. However, any geological interpretation of the global albedo pattern discovered in our study must be seen in the light

of the very low spatial resolution of the Voyager images of Umbriel. A global quasi-polygonal, low-contrast albedo pattern definitely exists on Umbriel. Limited topographic data suggest that a correlation between albedo and topography exists. The geological interpretation of these patterns is uncertain. □

## Influence of long-range transport of combustion emissions on the chemical variability of the background atmosphere

Hiram Levy II & Walter J. Moxim

Geophysical Fluid Dynamics Laboratory/NOAA, Princeton University, PO Box 308, Princeton, New Jersey 08542, USA

MAUNA Loa Observatory, located 3,400 m above sea level on the island of Hawaii in the middle of the Pacific Ocean, is a critical site for determining the background chemical reactivity of the unpolluted atmosphere and for monitoring its rate of change on a global scale. However, recent measurements of soluble nitrogen (principally  $\text{HNO}_3$ ) at the observatory find mixing ratios rising from their expected background values of 0.02–0.03 parts per  $10^9$  by volume (p.p.b.v.) in the winter to 0.07–0.12 p.p.b.v. in late summer with three-hour events as high as 0.25 p.p.b.v. (ref. 1). This raises the specific question of contamination by the long-range transport of pollution<sup>1</sup> and a broader question of the chemical variability of the background atmosphere. Here we show that a general circulation transport model which simulates the global spread and deposition of emissions from fossil-fuel combustion can reproduce the nitrogen measurements at the Mauna Loa Observatory. By isolating individual source regions, we show that US emissions are responsible for the late summer increase and that Asian emissions cause a smaller increase in the spring. These simulations, together with the earlier observations, indicate frequent contamination of the Mauna Loa Observatory by the long-range transport of reactive trace gases, such as  $\text{HNO}_3$ , and suggest a highly variable background atmosphere. It is essential that we are aware of such variability in order to discern anthropogenic effects on the atmosphere.

We use a global transport model which has already demonstrated the important role of dry deposition in acid deposition over North America<sup>2</sup> and the impact of combustion nitrogen on the global nitrogen budget<sup>3</sup>. The model has 11 altitude levels (31.4, 22.3, 18.8, 15.5, 12.0, 8.7, 5.5, 3.1, 1.5, 0.5 and 0.08 km), a horizontal grid size of ~265 km, and a time step of ~26 min (ref. 4). Using the 6-h time-average winds and precipitation provided by a parent general circulation model<sup>5,6</sup>, the collection of gaseous and particulate reactive nitrogen compounds that result from the combustion emissions are transported as a single tracer,  $\text{NO}_y$ . We have already discussed the formulation of tracer transport<sup>3,4</sup>, the global source of nitrogen resulting from fossil-fuel combustion<sup>3</sup>, the effective dry deposition of  $\text{NO}_y$ <sup>3,7</sup> and the effective removal of  $\text{NO}_y$  by precipitation<sup>3,4</sup>.

Those emissions not deposited in the source region become

FIG. 2 *a*, Composite polar stereographic projection of four Voyager images of Umbriel. Arrow A–A' identifies the projected location of the limb from image FDS 26840.04 (Fig. 1*b*). *b*, Plot of normal albedos from *a*, along section A–A'. *c*, Elevation profile along section A–A', corresponding to albedo plot in *b*.

available for long-range transport. This available  $\text{NO}_x$  is specified by basing the model's dry deposition and precipitation removal on measurements of nitrogen deposition in precipitation and of surface concentrations of individual nitrogen species. A single linear parameter is adjusted to bring the model's yearly integral of precipitation removal over North America into agreement with observation<sup>2</sup>. This same parameter leads to a good simulation of the yearly wet deposition of nitrogen over the European source region and remote locations in the Northern Hemisphere<sup>3</sup>. Dry deposition uses effective deposition velocities for  $\text{NO}_x$  which are based on the surface concentrations of the individual reactive nitrogen species measured over the United States.

The collective transport and parameterized deposition of  $\text{NO}_x$  precludes the explicit transport of individual nitrogen compounds, particularly insoluble species, such as peroxyacetyl nitrate (PAN) and other organic nitrates. However, we find that much of the transport from Asia and North America to the central Pacific is in stable subsiding air with little precipitation, and that the simulated  $\text{NO}_x$  deposition and surface concentrations in the central Pacific agree reasonably with observations<sup>3</sup>. The controlling factor is the model's meteorology—which both lifts the  $\text{NO}_x$  into the free troposphere (that region of the troposphere that is not directly influenced by boundary-layer mixing) and transports it to Hawaii—and not the detailed chemistry in the source region and along the transport path.

In Fig. 1, we compare the measurements of soluble nitrogen at the Mauna Loa Observatory<sup>1</sup> with the simulated monthly average mixing ratios of  $\text{NO}_x$  in grid boxes located over Hawaii. The model's simulation of  $\text{NO}_x$  at 940-mbar level in the atmosphere,  $\sim 0.5$  km above sea level, reproduces both the magnitude and seasonal variation of the observations from the Mauna Loa Observatory. In contrast, the simulated mixing ratios at the 685-mbar level, approximately the height of the Mauna Loa Observatory, agree only with the low winter levels and show no increase in the other seasons. The model does not have sufficient horizontal and vertical resolution to simulate the island of Hawaii, let alone the two mountain peaks and the local complex flow. It simulates long-range transport to grid boxes in the vicinity of Hawaii, and the 685-mbar grid box represents the free troposphere over the Pacific rather than the Mauna Loa Observatory.

Furthermore, extremely high-resolution ( $10 \text{ km} \times 10 \text{ km}$ ) simulations of the air flow around Hawaii show that the normal winds at 3,400 m in the free troposphere are greatly modified by the mountainous terrain<sup>9</sup>. Air parcels are carried up from below in direct flow from the windward side of the mountain and also in return flow from eddies that form in the lee of the island. As a result, the air sampled at the Mauna Loa observatory is a complex mixture of normal free-tropospheric air found at 3,400 m, air from stable layers below 3,400 m and above the maritime boundary layer, air from the maritime boundary layer (that is, below the maritime inversion layer and above the sea surface) and air from the island's boundary layer, which is likely to be contaminated by local pollution and natural emissions. Coincident measurements of humidity, wind direction and condensation-nuclei concentration are used to delete soluble nitrogen observations that may be contaminated by local pollution and natural emissions from both the island and the sea<sup>1</sup>, but measurements in air from stable layers below 3,400 m are retained. Over the ocean, the model produces a stable layer above a weakly mixed maritime boundary layer that is  $\sim 1.5$  km thick with a well mixed lowest level of  $\sim 0.2$  km. This structure is in qualitative agreement with the observed maritime boundary layer over the eastern tropical Pacific<sup>8</sup>, although the observed thickness increases from  $\sim 0.5$  km near the Baja to 1.5–2.0 km near Hawaii.

By running separate integrations for the global, Asian and US sources, we are able to identify the individual contributions. The observed summer mixing-ratio maximum, which is well

simulated in the model at 940 mbar, results from a sharp increase in transport from the United States to Hawaii that continues through the autumn. During the winter and spring, nitrogen emissions from Asia dominate and produce the spring increase. The low background levels at the 685-mbar level, with a hint of a spring maximum, are completely dominated by emissions from Asia, with little contribution from the United States or the rest of the globe.

A more complete picture of the atmospheric transport is provided by the simulated time series of  $\text{NO}_x$  at the 940-mbar level over Hawaii in Fig. 2. We see a collection of discrete transport events superimposed, at a frequency of 3–5 days, over a very low background. In particular, we see that the summer maximum is the result of a few large events. The limited observations appear to have a similar character (B. J. Huebert, personal communication). Both this simulation and the observations at Mauna Loa Observatory suggest that the levels of reactive gases in the remote atmosphere may be highly variable.

During the summer, in both the model and the real atmosphere, the time-mean Pacific subtropical high moves from a latitude of  $\sim 20^\circ \text{N}$  off the Baja to a position north of Hawaii at  $\sim 35^\circ \text{N}$  (ref. 10). At times, this produces a subsiding flow in the lower troposphere from the south-west United States and Mexico to Hawaii. When combined with surface transport from the source regions and small-scale vertical mixing over arid land, episodic transport of  $\text{NO}_x$  to the vicinity of Hawaii occurs in the model. Three-dimensional trajectories and a detailed

FIG. 1 Ten-day averages of soluble-nitrogen measurements at Mauna Loa Observatory compared with simulated monthly average mixing ratios of  $\text{NO}_x$  in the 940-mbar and 685-mbar grid boxes located over Hawaii. The dark shaded portion represents the simulated contribution of the US source, and the lighter shading represents the contribution from Asia (in our model a source region bounded on the south by the Equator, on the north by  $60^\circ \text{N}$  latitude, on the west by  $50^\circ \text{E}$  longitude and on the east by  $150^\circ \text{E}$  longitude) and the white area under the solid line represents the contribution from the rest of the globe, principally Mexico, Central America and Europe. The observations are represented by large black dots.

FIG. 2 The  $\text{NO}_y$  time series at the 940-mbar level in the vicinity of Hawaii constructed with instantaneous values taken every six hours from the simulation for a global source of combustion nitrogen.

synoptic analysis were used to identify this complex transport process (W.J.M., manuscript in preparation).

When using observed wind data, vertical velocity is not available and one must approximate atmospheric motion by assuming that either pressure or potential temperature remains constant. Such approaches can be misleading. Robinson and Harris<sup>11</sup> use observed winds to calculate approximate trajectories on constant-pressure surfaces for a number of actual transport events at Mauna Loa Observatory in August. Finding that none of the 700-mbar back-trajectories from Hawaii returned to the United States and none of the 850-mbar trajectories from the United States approached Hawaii, they conclude that US emissions are not involved<sup>11</sup>. We believe that the actual summertime transport events are as complex as those simulated by the model and cannot be represented by trajectories on constant-pressure surfaces.

The transport of  $\text{NO}_y$  from Asia is composed of a large number of relatively small ( $\sim 0.1$  p.p.b.v.) events. Asian dust, which also has surface sources and is removed by precipitation, may serve as a surrogate for Asian emissions. The dust has been observed throughout the central Pacific, including Mauna Loa, and has a spring maximum<sup>12,13</sup>. Nitrogen emissions from Asia are expected to follow a similar transport path. To reach Hawaii in the subtropics, the Asian emissions must first be lifted into the free troposphere by storms and carried eastward and north-eastward over the central Pacific. Then the  $\text{NO}_y$  must be caught in descending air, transported anticyclonically (clockwise) towards the Equator and carried far enough south to be caught in the low-level easterly flow. Such paths have been determined for actual springtime Asian dust events<sup>14</sup> and for our simulated springtime transport of Asian  $\text{NO}_y$ . Both the lifting over Asia and the descent over the Pacific occur at a range of levels in the troposphere. As a result, the model's Asian emissions are dispersed throughout the lower troposphere. In contrast, the transport from North America is descending all the way to Hawaii in the stable flow of the Pacific subtropical high and should arrive just above the maritime boundary layer.

Based on these results, other model studies<sup>9</sup>, observations<sup>12,13</sup> and actual climatology<sup>10</sup>, we conclude that the maximum in soluble nitrogen observed at Mauna Loa Observatory in the summer and autumn is a result of US fossil-fuel combustion. It travels to Hawaii in stable descending air and is carried up to the observatory by the complex flow associated with the mountain orography. Springtime measurements in the vicinity of Hawaii, but away from the influence of the island's orography, should find episodes of elevated  $\text{NO}_y$  (mainly from Asia) up into the middle troposphere, while summertime measurements should find episodes of elevated  $\text{NO}_y$  concentrated in shallow layers just above the maritime boundary layer. □

## Synthesis of bulk superconducting $\text{YBa}_2\text{Cu}_3\text{O}_x$ at one atmosphere oxygen pressure

R. J. Cava, J. J. Krajewski, W. F. Peck Jr, B. Batlogg, L. W. Rupp Jr, R. M. Fleming, A. C. W. P. James & P. Marsh

AT&T Bell Laboratories, Murray Hill, New Jersey 07974, USA

THE well-known 90-K superconductor  $\text{YBa}_2\text{Cu}_3\text{O}_7$  ('123') is the first ( $n=0$ ) member of a homologous series of compounds with the general formula  $\text{Y}_2\text{Ba}_4\text{Cu}_{6+n}\text{O}_{14+n}$ . These compounds combine layers of copper–oxygen pyramids with single and/or double copper–oxygen chains. The  $n=2$  member,  $\text{YBa}_2\text{Cu}_4\text{O}_8$  ('124'), with double Cu–O chains, and the  $n=1$  ytterbium analogue,  $\text{Yb}_2\text{Ba}_4\text{Cu}_7\text{O}_{15}$  ('247'), which mixes single and double chains, were first observed as intergrowths in bulk 123 by electron microscopy<sup>1,11</sup>. The 124 phase was then synthesized as a majority phase in thin films<sup>2,3,12</sup>, and its crystal structure was determined<sup>4</sup> and found to be in agreement with the model proposed from microscopy. An important advance in the synthesis of bulk materials, the result of extensive pressure–temperature phase equilibria studies, was the isolation of 124 and 247 at oxygen pressures of  $>200$  atm, and detailed determinations of their crystal structures (see, for example, refs 5–9). High-pressure studies have also shown that the 124 phase could be made with many rare-earth elements<sup>13</sup>. Here we report the synthesis of the 124 phase in pure bulk form by a novel synthetic route in a flowing oxygen stream at 1 atm pressure. This technique allows  $\text{YBa}_2\text{Cu}_4\text{O}_8$  to be synthesized without specialized equipment, will make it generally available for study of its normal and superconducting properties, and will make possible more extensive comparisons with  $\text{YBa}_2\text{Cu}_3\text{O}_7$  and other high- $T_c$  superconductors. Our results suggest that 124 is the thermodynamically stable phase at low temperatures and 1 atm pressure, under oxidizing conditions; the usual inability to synthesize it in these conditions is probably due to the limitations of reaction kinetics.

The synthesis is a two-step process. In the first step, starting materials are mixed in the correct stoichiometric proportion and heated very slowly to 750 °C in dense, oversized  $\text{Al}_2\text{O}_3$  crucibles. They are then allowed to react for 16–24 h. All heating, soaking and cooling is carried out in flowing  $\text{O}_2$ . Best results are obtained when an intermediate mixing-and-grinding step is performed after the first few hours of reaction at 750 °C. Different combinations of starting materials yield slightly different results. We investigated three different sets of starting materials: (1)  $\text{Y}(\text{NO}_3)_3 \cdot x\text{H}_2\text{O}$ ,  $\text{Ba}(\text{NO}_3)_2$  and  $\text{Cu}(\text{NO}_3)_2 \cdot x\text{H}_2\text{O}$ ; (2)  $\text{Y}(\text{NO}_3)_3 \cdot x\text{H}_2\text{O}$ ,  $\text{Ba}(\text{NO}_3)_2$  and  $\text{CuO}$ ; and (3)  $\text{Y}_2\text{O}_3$ ,  $\text{Ba}(\text{NO}_3)_2$  and  $\text{CuO}$ . The first of these, with all materials present as nitrates, always yielded the most phase-pure materials, although 124 did occur as the major phase for all three sets of starting materials. As it was necessary to use hydrated nitrates, the amount of water in the starting materials was determined directly by weight loss on decomposition to the simple oxides, which indicated that

FIG. 1 Powder X-ray diffraction pattern of  $\text{YBa}_2\text{Cu}_4\text{O}_8$  prepared using a sodium carbonate catalyst. Peaks are indexed on an A-centred orthorhombic cell with lattice parameters  $a = 3.846$ ,  $b = 3.871$ ,  $c = 27.262$  Å. Impurity peaks are marked with crosses.

our starting materials were  $\text{Y}(\text{NO}_3)_3 \cdot 5.8\text{H}_2\text{O}$  and  $\text{Cu}(\text{NO}_3)_2 \cdot 3.3\text{H}_2\text{O}$ .

In the second step, the pre-reacted powder, after grinding, is mixed with an approximately equal volume of alkali carbonate powder. The alkali carbonate acts to catalytically enhance the reaction rate. For the synthesis of 124, either  $\text{Na}_2\text{CO}_3$  or  $\text{K}_2\text{CO}_3$  can be used for this purpose, but  $\text{Na}_2\text{CO}_3$  yields better phase purity. The 124-carbonate mixture is ground, placed in silver-foil packets or crucibles and heated at  $800^\circ\text{C}$  in flowing  $\text{O}_2$  for 3 days. The carbonates are not molten at this temperature.  $\text{YBa}_2\text{Cu}_4\text{O}_8$  is the main phase present after just one day, but the phase purity improves for longer reaction times. If the first reaction step is not carried out,  $\text{BaCO}_3$  forms in the initial stages of the carbonate reaction and the desired phase cannot be made. The 124 phase can also be made, albeit less reliably, at  $825^\circ\text{C}$ ; but by  $850^\circ\text{C}$ ,  $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$  forms as a major impurity phase, which is consistent with the metastability of  $\text{YBa}_2\text{Cu}_4\text{O}_8$  described in ref. 8. We are able to make 124 as the majority phase at temperatures as low as  $700^\circ\text{C}$  by this process. At the lowest temperatures, approximately equal mixtures of  $\text{K}_2\text{CO}_3$  and  $\text{Na}_2\text{CO}_3$  function as the most effective catalysts, as such a mixture is closer to its melting point during the reaction than is either of the pure carbonates. After reaction, the products are washed briefly (15 min) in water to remove excess alkali carbonate and dried by gentle heating in air. The product is a fine-grained powder.

A representative powder X-ray diffraction pattern of the material produced by this technique is shown in Fig. 1. The peaks have been indexed by position and by the intensities calculated from the published crystal structure. The materials made by this method, although in general not perfectly single-phase, are at least as phase-pure as materials prepared at high oxygen pressures. Three impurity peaks are present in Fig. 1 with intensities of  $\sim 10\%$  of the main peak intensity, at  $d$  values (inter-planar spacings) of  $2.83$  Å,  $2.92$  Å and  $2.32$  Å ( $\text{CuO}$ ). For the  $\text{Na}_2\text{CO}_3$ -catalysed formation of 124 at  $800^\circ\text{C}$ , the 123 phase is not usually present as an impurity, but it may be present if  $\text{K}_2\text{CO}_3$  is used as the catalyst. Improved phase purity may be

achieved by careful control of the composition and uniformity of the hydrated-nitrate starting materials, or of the initial stages of the dehydration process, which involves the evolution of a large amount of gas from a mixture which is apparently molten at very low temperatures ( $100$ – $200^\circ\text{C}$ ). Least-squares refinement of the crystallographic unit cell from 17 of the powder diffraction peaks between  $2\theta$  values of  $30^\circ$  and  $62^\circ$ , consistent with an A-centred orthorhombic cell, yields lattice parameters  $a = 3.8457(9)$ ,  $b = 3.8711(9)$  and  $c = 27.2616(61)$  Å, in excellent agreement with the orthorhombic cell parameters published previously<sup>9</sup>.

Figure 2 shows the results of d.c. magnetization measurements on  $\text{YBa}_2\text{Cu}_4\text{O}_8$  prepared at  $800^\circ\text{C}$  in  $\text{O}_2$  with  $\text{Na}_2\text{CO}_3$  as catalyst. The sample is a pellet pressed from the fine-powder product, but not sintered. The measurements were made using an SHE squid magnetometer in a field of  $25$  Oe. Flux expulsion below  $T_c$  (on field-cooling) corresponds to  $\sim 60\%$  of that expected for a perfect diamagnet. This is a large apparent superconducting volume fraction for a pressed-powder sample, and actually represents a conservative lower limit for the true fraction of superconducting material, because flux trapping in pores may in general limit the flux expulsion significantly, as is evident here in the slowly increasing diamagnetism measured at temperatures well below the superconducting transition. The transition temperature ( $77$  K) is within the range of temperatures reported previously but is somewhat lower than the maximum of  $80$ – $81$  K reported for  $\text{YBa}_2\text{Cu}_4\text{O}_8$  prepared at high oxygen pressures. The reason for this variation is not yet clear, as the compound has been reported to be stoichiometric in composition for all components, including oxygen<sup>5</sup>. Annealing our material at  $450^\circ\text{C}$  in flowing  $\text{O}_2$  for 16 h did not increase  $T_c$  substantially. There is no diamagnetism above  $77$  K, indicating, as did the powder X-ray diffraction data, that  $\text{YBa}_2\text{Cu}_3\text{O}_7$  is not present as an impurity under these synthetic conditions.

We have also measured the temperature dependence of the crystallographic cell parameters between  $30$  and  $320$  K. We were particularly interested to see whether structural anomalies occur near  $240$  K, where kinks in the resistance and Hall coefficient have been observed in thin-film samples (ref. 10 and S. Martin *et al.*, manuscript in preparation). The temperature dependence was measured by taking  $\theta$ – $2\theta$  scans at moderately high angles ( $56$ – $63^\circ 2\theta$ ) and fitting to the positions of six peaks of the powder pattern. The instrumental resolution was  $\sim 0.028$  Å<sup>–1</sup> full width at half maximum. The results of the fits (Fig. 3) do not indicate any anomalies in the lattice parameters in the range  $30$ – $320$  K. In addition, we observed no indication of a lower symmetry in

FIG. 2 Temperature dependence of d.c. magnetization for a pressed-powder compact of  $\text{YBa}_2\text{Cu}_4\text{O}_8$ , measured in a d.c. field of  $25$  Oe. Zero-field cooled (zfc) and field-cooled (fc) measurements are shown.

FIG. 3 Temperature dependence of the crystallographic unit-cell parameters for  $\text{YBa}_2\text{Cu}_4\text{O}_8$  between 30 and 320 K.

the powder scans at 30 K, nor were extra peaks observed that would indicate a multiplication of the unit-cell volume.

In conclusion, we have shown that the compound  $\text{YBa}_2\text{Cu}_4\text{O}_8$  can be prepared as a bulk phase at ambient pressure in a novel multi-step process which employs an alkali carbonate to enhance the reaction rate. Special care must be taken in the selection of the starting materials, the order of the reaction steps, selection of the container materials, the temperature of reaction, and the use of a non-detrimental reaction-rate enhancer. The process described here yields high-quality 124 without specialized equipment and will allow considerably more research to be performed on its physical properties. Finally, we note that our attempts to synthesize  $\text{Y}_2\text{Ba}_4\text{Cu}_7\text{O}_{15}$  by the same method were not successful. □

## Separation of paramagnetic and diamagnetic molecules using high- $T_c$ superconducting ceramics

Shimon Reich\* & Israel Cabasso†

\* Department of Materials Research, Weizmann Institute of Science, Rehovot, Israel 76100

† State University of New York–ESF, Syracuse, New York 13210, USA

WITH the advent of high-temperature superconductivity, the search is on for applications of these materials. Here we outline a new method for the separation of paramagnetic and diamagnetic molecules using the repulsive interaction between a magnetic dipole and a micro-cavity in a ceramic material which is in the supercon-

TABLE 1  $\text{O}_2/\text{N}_2$  ratio in out-flow gas through  $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$  and a  $\text{YBa}_2\text{Cu}_3\text{O}_6$ -rich pellet as a function of temperature

ducting state. We present experiments of the permeation of air through  $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$  and through  $\text{Bi}_{1.8}\text{Pb}_{0.2}\text{Ca}_2\text{Sr}_2\text{Cu}_3\text{O}_x$  ceramic pellets. These experiments show the preferential permeability of nitrogen compared with that of oxygen in the diamagnetic state of the superconductors below the critical transition temperature,  $T_c$ . This effect is quenched by the application of a large enough external magnetic field. As far as we know it is the first application of the porosity of the ceramic superconductors.

The energy of interaction ( $E$ ) of a magnetic dipole ( $m$ ) and a superconducting wall is easily calculated by the mirror principle<sup>1</sup> (see Fig. 1). This interaction is given by:

$$E = \frac{\bar{m}_1 \bar{m}_2}{r^3} - \frac{3(\bar{m}_1 \bar{r})(\bar{m}_2 \bar{r})}{r^5} = \frac{m^2}{r^3} \{\cos \varepsilon - 3 \cos \theta_1 \cos \theta_2\} \quad (1)$$

where  $\bar{m}_2$  is the mirror image of  $\bar{m}_1$ , and  $\theta_1 + \theta_2 = 180^\circ$ . The thermal tumbling of  $\bar{m}$ , when averaged over all orientations  $\theta$ , gives  $\langle E \rangle = \frac{2}{3} (m^2/r^3)$ . Suppose we enclose the tumbling magnetic dipole in the centre of a cubic cavity: at what distance from the walls of the cavity is the repulsive interaction of the superconducting walls equal to the thermal kinetic energy of the elementary magnetic moment? We have  $6\langle E \rangle = \frac{2}{3} kT$ , and thus  $r = (6m^2/kT)^{1/3}$ . We can now substitute  $m^2$  by the paramagnetic susceptibility  $\chi(T) = m^2 N/3kT$ , where  $N$  is Avogadro's number, so that

$$r = \left( \frac{18\chi(T)}{N} \right)^{1/3} \quad (2)$$

From equation (2) we can estimate the effective distance  $r$  at which the repulsive interaction between the molecular magnetic moment and the superconducting diamagnetic enclosure will strongly affect the thermal diffusivity of the magnetic dipole. Let us compare the relevant size parameters for oxygen (a paramagnetic molecule) to those of diamagnetic nitrogen. The effective molecular diameter of oxygen, as derived from the Einstein-Stokes equation using the diffusion constant of  $\text{O}_2$  in ethanol<sup>2</sup>, is 1.67 Å, and the same calculation for  $\text{N}_2$  in carbon tetrachloride yields 1.24 Å; in comparison,  $2r$  for oxygen (using  $\chi(91 \text{ K}) = 1.08 \times 10^{-2} \text{ ml mol}^{-1}$  (ref. 3)) is 1.37 Å. Nitrogen, on the other hand, is diamagnetic,  $\chi(300 \text{ K}) = -12 \times 10^{-6} \text{ ml mol}^{-1}$ . We see that the diameter,  $2r$ , is comparable with the effective diameter as calculated from the Einstein-Stokes equation. The Pauling dimensions for  $\text{O}_2$  are 2.8 Å in width and 3.9 Å in length, with a kinetic diameter  $\sigma = 3.46$  Å. The corresponding values for nitrogen are 3.0 Å, 4.1 Å and 3.64 Å respectively<sup>4</sup>. The apparently small difference in the kinetic diameters of these two gases is thought to be one of the main reasons why zeolites and glassy polymers show preferential sorption and permeation of oxygen relative to nitrogen<sup>5,6</sup>. We expect therefore that the repulsive interaction will increase the effective kinetic diameter of oxygen. Thus if air is diffused through a superconducting ceramic material at  $T < T_c$ , we expect preferential permeability of nitrogen, provided that the average pore diameter is low enough ( $\sim 10$  Å). We examine, as an example, the possibility of preferential permeability of nitrogen over that of oxygen

through  $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$  in the diamagnetic state. Such a separation process is expected to take place for a diffusion-controlled permeation of air through the superconducting pellet in the temperature range in which the diamagnetic susceptibility is fully developed. (The Meissner onset temperature in our samples was 102 K and the diamagnetic effect was fully developed at  $\sim 77$  K.) The permeation experiment was therefore performed using a low-pressure gradient of 50 kPa starting at the lowest temperature possible, just above the dew point of air (81.3 K at 100 kPa (ref. 7)). Below the dew point, the results of the permeation experiments are obscured by the gas-liquid equilibria of oxygen and nitrogen.

We conducted an experiment (see Fig. 2) in which dry air was passed over and diffused through a  $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$  pellet, 13 mm in diameter and 1 mm thick, mounted in a brass block cooled by liquid nitrogen. The composition of the outflow gas ( $\sim 0.4$  ml  $\text{min}^{-1}$  at 26 °C) was analysed by a gas chromatograph in real time. The resulting run, measured at a heating rate of 0.1 K  $\text{min}^{-1}$ , in the temperature range between 82 K and 92 K, is shown in Fig. 3a. The critical transition temperature ( $T_c$ ) for this pellet was  $92 \pm 0.5$  K, and the temperature dependence of the resistance is shown in Fig. 4a. This sample was quite porous, its specific density  $\rho = 5.64$  g  $\text{cm}^{-3}$  being comparable with the specific theoretical density  $\rho_{\text{th}} = 6.4$  g  $\text{cm}^{-3}$ .

In a control experiment a  $\text{YBa}_2\text{Cu}_3\text{O}_6$ -rich pellet was prepared by a fast quench of a  $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$  pellet from 900 °C to liquid-nitrogen temperatures. This sample did not exhibit the Meissner effect and a plot of resistance against temperature is shown in Fig. 4b. This pellet was similar in density and micro-grain structure to the superconducting sample used above. It is apparent from comparison of the plots in Fig. 3a and b that

the superconducting sample does impede the mobility of  $\text{O}_2$  for  $T < 83$  K, and indeed shows preferential permeability for nitrogen in comparison with that of the control. This trend is followed by a sharp desorption of the trapped oxygen for  $T \approx 85$  K; the permeate stream composition subsequently tails off to the  $\text{O}_2/\text{N}_2$  ratio of 0.268, which is that observed in air.

We suggest that the experimental results may be interpreted as the manifestation of preferential permeability of nitrogen over that of oxygen in a temperature range in which the diamagnetism of the ceramic material is strong, followed by desorption of oxygen upon the increase of the magnetic susceptibility in the pellet.

In another experiment the relative permeation of  $\text{O}_2$  against  $\text{N}_2$  was measured through a 9-mm-thick  $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$  pellet and through a  $\text{YBa}_2\text{Cu}_3\text{O}_6$ -rich sample of the same geometry using a pressure gradient of 80 kPa and a flow rate of  $\sim 0.2$  ml  $\text{min}^{-1}$ . The results, in the temperature range 85–88 K measured at a heating rate of 0.1 K  $\text{min}^{-1}$ , are presented in Table 1. In this experiment high selectivity is observed, with  $(\text{O}_2/\text{N}_2)_{\text{air}}/(\text{O}_2/\text{N}_2)_{\text{permeate}} \approx 5$ .

We expect that the application of a magnetic field,  $H > H_c$ , to the diamagnetic membrane in the superconducting state will quench the selectivity for nitrogen against oxygen permeation that is observed for  $T < T_c$  and  $H = 0$ .  $\text{Bi}_{1.8}\text{Pb}_{0.2}\text{Ca}_2\text{Sr}_2\text{Cu}_3\text{O}_x$ , a ceramic with a high  $T_c$  ( $111 \pm 1$  K) and low  $H_c$  ( $< 100$  Oe at 4.2 K), was prepared to test this prediction. The permeation experiment was conducted through a 2-mm-thick pellet using a pressure gradient of 50 kPa, a flow rate of 0.4 ml  $\text{min}^{-1}$  and a

FIG. 4 Resistance against temperature for a, a  $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$  pellet, and b, a  $\text{YBa}_2\text{Cu}_3\text{O}_6$ -rich pellet.

heating rate of  $0.1 \text{ K min}^{-1}$ . Figure 3c, d shows the results for a magnetic field ( $H=0$  and  $H=220 \text{ Oe}$ ) applied perpendicularly to the surface of the pellet. The measured selectivity is shifted to a higher temperature range than that observed for  $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$  (see Fig. 3a, b) as is the desorption peak, which is at  $\sim 102 \text{ K}$  for the zero-field run. A field of  $220 \text{ Oe}$  is large enough to quench the selectivity effect as the magnetic flux penetrates the diamagnetic membrane. (Note that at  $\sim 100 \text{ K}$ ,  $H_{c1} < 20 \text{ Oe}$ .)  $\square$

## Different behaviour of platinum in the Indian and Pacific Oceans

G. S. Jacinto\* & C. M. G. van den Berg†

Oceanography Laboratories, Department of Earth Sciences, The University, Liverpool L69 3BX, UK

THERE is little known about the chemical behaviour of the platinum-group metals in the ocean. Here we have used cathodic stripping voltammetry<sup>1</sup> to determine the concentration of dissolved platinum in the water column of the Indian Ocean. The range of Pt values obtained ( $0.2\text{--}1.6 \text{ pM}$ ) is similar to that found previously in the Pacific Ocean<sup>2-4</sup>. But unlike the earlier Pacific Ocean investigations which depicted platinum as having nutrient-like behaviour, our data show that in the Indian Ocean the element is scavenged down the water column and so is depleted with depth. This is consistent with the predominant oxidation state of platinum in oxygenated sea water being Pt(IV), which is also predicted from thermodynamic considerations and the association of platinum with manganese nodules in sediments<sup>5</sup>. The data show that platinum co-varies in the water column with dissolved manganese, the concentration of Pt being lower than Mn by a factor of about 600. But the residence time of Pt in the oceans is longer than that of Mn, as revealed by a Pt/Mn ratio in the Indian Ocean that is 300 times higher than in crustal rock.

Seawater samples were obtained at  $27^\circ 00' \text{ S}$ ,  $56^\circ 58' \text{ E}$  (station CD 1504) and  $06^\circ 09' \text{ S}$ ,  $50^\circ 54' \text{ E}$  (station CD 1507) during cruise 15 of the RRS *Charles Darwin* in the Indian Ocean<sup>5</sup>. Clean laboratory and sampling procedures were used to avoid sample contamination<sup>6</sup>. The samples were collected using 10-litre polytetrafluoroethylene-lined Go-Flo bottles mounted on a rosette with conductivity, temperature and depth measuring instrumentation. The sea water was immediately filtered under pressure through acid-washed  $0.4 \mu\text{m}$  'Nucleopore' filters in teflon filter holders into acid-washed high-density polyethylene bottles and stored frozen. Before analysis, samples were thawed and acidified to pH 2 with HCl (Aristar grade), and a period of at least a week was allowed to elapse for desorption from the bottle walls and dissolution of any particulates formed in the process of freezing and thawing. The samples were then irradiated with ultraviolet light for 6–8 hours to break down

organic material such as surfactants and complexing ligands.

Dissolved platinum was determined by cathodic stripping voltammetry<sup>1</sup>. When sulphuric acid ( $0.5 \text{ M}$ ), hydrazine ( $0.0015\%$ ) and formaldehyde ( $0.012\%$ ) were added to a  $10 \text{ ml}$  aliquot of each sample, the formazone produced formed a complex with Pt(II). A small constant fraction of this complex is adsorbed on a hanging mercury drop electrode during a preconcentration stage that lasts for 5 min and catalyses the formation of hydrogen when the electrode potential is scanned in a negative direction. The reduction current associated with this hydrogen formation is linearly related to the combined Pt(II) and Pt(IV) concentration<sup>1</sup>. Supplementary data such as the temperature, salinity, amounts of dissolved oxygen, nutrients and other metals were obtained during the cruise and are described elsewhere<sup>5,6</sup>.

The vertical distribution of platinum, manganese and salinity at stations CD 1504 and CD 1507 is shown in Figs 1 and 2. Depletion with depth is shown in both Pt profiles and for Mn. The drop in the Pt concentrations in the upper water column occurs at a depth that is shallower at station CD 1507 than at station CD 1504. This is consistent with upwelling at station CD 1507 and with downwelling at station CD 1504, as evidenced by the shape of the nutrient/depth profiles.

Some co-variation of Pt and Mn is apparent from a linear regression of the Pt concentration (pM) as a function of the Mn concentration (nM) ( $[\text{Pt}] = a[\text{Mn}] + b$ ), where  $a = 1.06 \pm 0.28$  and  $b = 0.30 \pm 0.31$ . The standard deviations are quite large because of the variation in Mn concentrations in the deep waters (the Mn concentrations were almost at the limit of detection) and because of a scarcity of data for the upper water column, where most of the change in the platinum concentration occurs. Analysis of a number of samples without prior ultraviolet photolysis showed that interference by dissolved organic material, presumably consisting of surface-active as well as chelating compounds, was particularly strong in the upper water column. But this interference was removed in the ultraviolet-photolysis step, as was apparent from the voltammetric sensitivity (the ratio of the reduction current over the platinum concentration), which was constant for samples from all depths.

The ratio of crustal Mn to Pt is  $\sim 2 \times 10^5$  (crustal data from Govett<sup>7</sup>), whereas the ratio of Mn to Pt in sea water is  $\sim 600$ . Thus platinum is significantly enriched relative to manganese in sea water compared with its crustal value, which suggests that platinum is not as efficiently scavenged as manganese, and has a longer residence time. Calculation of the inorganic speciation of Pt(II) in sea water using published stability constants<sup>8</sup> shows that it occurs largely (98%) as the  $\text{PtCl}_4^{2-}$  complex (which is an anion, and would tend to behave conservatively), the rest being made up of  $\text{PtCl}_3^-$  complexes. The overall  $\alpha$ -coefficient<sup>9</sup> of complexation of Pt(II),  $\alpha_{\text{Pt}} = [\text{Pt}_T]/[\text{Pt}^{2+}]$ , where  $[\text{Pt}_T]$  is

the total Pt(II) concentration, is calculated from  $\alpha_{\text{Pt}} = 1 + \sum K_{\text{PtCl}_i} [\text{Cl}^-]^i$  (hydrolysis of  $\text{Pt}^{2+}$  is negligible in the presence of  $\text{Cl}^-$ ) and has a value of  $10^{12}$ . The much greater value for  $\alpha_{\text{Pt}}$  than for  $\alpha_{\text{Mn}}$  ( $\sim 2$ ; ref. 10) may explain the enrichment of Pt in sea water relative to Mn, as uncomplexed cationic Mn(II) would tend to be scavenged more easily than the anionic chloride species of Pt(II).

The profiles for Pt in the Indian Ocean are quite different from those obtained in earlier studies from the Pacific, which showed that the element behaved like a nutrient<sup>2-4</sup> (a comparative profile for Pt displaying this behaviour in the Pacific Ocean is illustrated in Fig. 2c). But because Pt is enriched relative to Pd in ferromanganese nodules, and because of the greater stability of Pt(IV) relative to Pd(IV), it has been proposed that Pt might also be subject to oxidative removal<sup>2,3</sup>. The reduction of Pt(IV) to Pt(II) in an electrolyte containing chloride ions (sea water) is described by<sup>11</sup>  $\text{PtCl}_6^{2-} + 2\text{e}^- \rightleftharpoons \text{PtCl}_4^{2-} + 2\text{Cl}^-$ , and has a value of 0.68 V for  $E^0$ . According to the Nernst equation, the ratio of Pt(II)/Pt(IV) in sea water depends on the potential,  $E$ ,

as  $E = 0.67 - 0.03 \log ([\text{PtCl}_4^{2-}]/[\text{PtCl}_6^{2-}])$ . The redox potential,  $E_{\text{H}}$ , of oxygenated water is determined by the  $\text{O}_2/\text{H}_2\text{O}$  redox couple and lies at  $E_{\text{H}} = 0.75$  V, whereas in surface sea water in the presence of  $10^{-7}$  M hydrogen peroxide<sup>12</sup> it is controlled by the  $\text{O}_2/\text{H}_2\text{O}_2$  couple and  $E_{\text{H}} = 0.40$  V. The calculated equilibrium ratio of Pt(II)/Pt(IV) amounts to  $10^9$  in surface waters, whereas in deeper oxygenated waters it is 0.002. Therefore the thermodynamically preferred oxidation state of Pt is Pt(IV) in most of the oceanic water column, whereas in surface waters it is Pt(II). The scavenged behaviour of Pt in the Indian Ocean is consistent with this thermodynamic prediction. But perhaps it is not consistent with the rather long residence time of Pt which would be about 300 times longer than that of Mn on the basis of the Pt/Mn ratio in the crust as compared with the ratio in seawater.

The deep-water concentration of Pt in the Indian Ocean is lower than in the Pacific, whereas the concentration in the upper water column is greater, but the cause of this difference is not clear. Perhaps it results from small differences in the  $E_{\text{H}}$  arising from variations in the dissolved oxygen concentration or of

FIG. 1 Vertical distribution of a, salinity b, manganese (from N. H. Morley, P. Statham & J. D. Burton, manuscript in preparation) and c, platinum in Station CD 1504.

FIG. 2 Vertical distribution of a, salinity b, manganese (from N. H. Morley, P. Statham & J. D. Burton, manuscript in preparation) and c, platinum in Station CD 1507; in c, the platinum concentration in the Pacific Ocean<sup>3</sup> (circles) is shown along that in the Indian Ocean (crosses).

localized inputs from hydrothermal (in the Pacific deep waters) or eolian (surface Indian Ocean waters) origin. The possibility cannot be discounted that the difference is caused by an experimental artefact, perhaps as a result of organic trace metal speciation. For instance, it is possible that the radioactive tracer<sup>3</sup> that was added to samples before Pt determination by GF-AAS, to verify the accumulation efficiency of the anion-exchange resin, did not reach equilibrium with organically complexed Pt. This is unlikely, as the samples were acidified to low pH; nevertheless, very stable metal-organic complexes such as of Cu and Ni occur in sea water<sup>13,14</sup>, and a small amount of organically complexed copper is stable in acidified samples<sup>15</sup>. Furthermore, it is not impossible that complexation of Pt(II) by natural ligands is much stronger than with Cu(II) or Ni(II) if we consider the high value for  $\alpha_{Pt}$  in sea water and the large shift in the reduction potential ( $>1$  V, equivalent to a value for  $\log \alpha_{Pt-formazine} > 30$ ) on complexation of Pt(II) by formazone before voltammetric analysis<sup>1</sup>. Such organic complexing material, if present, should have been removed in the ultraviolet-photolysis step and would therefore not interfere with the voltammetric determination of Pt.

The interesting chemistry of platinum in the oceans should be investigated further if indeed the redox properties of Pt(IV)/Pt(II) and the strong complexation of Pt(II) can account for the observed differences in the Pt concentrations in the Pacific and Indian oceans. □

## Oscillatory responses in cat visual cortex exhibit inter-columnar synchronization which reflects global stimulus properties

Charles M. Gray, Peter König, Andreas K. Engel & Wolf Singer

Max-Planck-Institute for Brain Research, Deutschordenstrasse 46, D-6000 Frankfurt am Main 71, FRG

A FUNDAMENTAL step in visual pattern recognition is the establishment of relations between spatially separate features. Recently, we have shown that neurons in the cat visual cortex have oscillatory responses in the range 40–60 Hz (refs 1, 2) which occur in synchrony for cells in a functional column and are tightly correlated with a local oscillatory field potential. This led us to hypothesize that the synchronization of oscillatory responses of spatially distributed, feature selective cells might be a way to establish relations between features in different parts of the visual field<sup>2,3</sup>. In support of this hypothesis, we demonstrate here that neurons in spatially

separate columns can synchronize their oscillatory responses. The synchronization has, on average, no phase difference, depends on the spatial separation and the orientation preference of the cells and is influenced by global stimulus properties.

We recorded multi-unit responses to appropriately oriented moving light bars simultaneously from 5 to 7 spatially separate sites in cortical area 17 of 13 adult cats. To determine the temporal relationship of the firing patterns recorded at two sites, we computed both the auto- and cross-correlation functions of the spike trains<sup>4,5</sup>. For 132 of 199 recording sites, the auto-correlation function of the responses was periodic, indicating that the neuronal responses were oscillatory. To establish an objective criterion for the occurrence of oscillatory responses, we fitted a damped sine wave (Gabor function) to the auto-correlograms. Responses were considered to be oscillatory when the fitted function had at least three peaks and when the amplitude of the sinusoidal modulation was significantly different from zero ( $P < 0.05$ ) and exceeded 10% of the amplitude of the cross-correlogram recomputed after shuffling the trial sequence by one stimulus period. The frequency of these oscillatory responses ranged from 40 to 60 Hz (mean,  $50 \pm 6$  Hz), was similar for different recording sites in the same animal and depended only slightly on stimulus configuration (orientation, direction)<sup>2</sup>. Of these 132 recordings, we selected 99 pairs in which oscillatory responses occurred simultaneously at two sites, and used these in cross-correlation analysis. Applying the same criteria used for auto-correlograms, 51 of the cross-correlograms had a significant correlation between the oscillatory responses.

Figure 1 illustrates a typical case in which neuronal responses were oscillatory and synchronized across spatially separate columns. Responses were recorded from five closely spaced sites near the representation of the area centralis of the retina. The receptive fields were overlapping but had different orientation preferences at adjacent sites. Stimulation with a light bar of  $112^\circ$  orientation evoked vigorous responses at sites 1, 3 and 5 but not at sites 2 and 4. As indicated by the periodic modulations of both auto- and cross-correlation functions, these responses were oscillatory and the oscillations were tightly correlated with zero phase difference. Changing the orientation of the stimulus to  $22^\circ$ , to maximize activation of the units at sites 2 and 4 produced synchronized oscillatory responses at these sites (data not shown). In all cases the correlations were abolished in the shuffled cross-correlogram<sup>4–11</sup>.

When the recording sites had a larger spatial separation ( $>2$  mm) the receptive fields were non-overlapping and could be stimulated independently. This enabled us to activate the

TABLE 1 Correlated oscillatory neuronal responses in area 17 as a function of spatial separation of recording sites and angular difference in preferred stimulus orientation

Angular difference of preferred orientation	Spatial separation	
	0.4–2.0 mm (overlapping fields)	2.0–7.0 mm (non-overlapping fields)
0–22°	90% (28/31)	54% (7/13)
45°	73% (8/11)	0% (0/8)
67–90°	44% (7/16)	25% (1/4)

Data were taken from a total of 99 cross-correlograms in which simultaneous oscillatory responses were recorded from two electrodes in area 17. Correlograms computed for responses at sites separated by 8–12 mm ( $n=16$ ) were excluded. The correlograms were classified into six categories based on the difference in orientation preference of the neurons at the two recording sites and whether or not the receptive fields were overlapping. The results are presented as the percentage of recordings showing oscillatory correlations. The numbers in parentheses correspond to the number of oscillatory correlations and the total number of response pairs analysed for that category, respectively. The correlograms which showed no periodic modulation (48 out of 99) showed either a single peak centred around a 0 ms time delay ( $n=11$ ) or a flat distribution ( $n=37$ ).

units at each site even if their preferred orientations differed and to determine more precisely if the extent of correlations depended on the similarity of orientation preferences. Figure 2 illustrates the typical case where oscillatory responses in remote columns were synchronized if their orientation preferences were similar but showed no fixed phase relationship when the orientation preferences differed.

In two individuals we recorded at two sites separated by 7 mm in which the receptive fields were non-overlapping, had the same orientation preference and were aligned colinearly. This enabled us to co-activate the units at both recording sites with a single long light bar, as well as with two short, independently moving stimuli (Fig. 3). In both cases, the stimuli evoked oscillatory responses at each site. When the short light bars were moved in opposite directions over the two receptive fields, the respective responses showed no phase locking. When the two stimuli were moved in the same direction, however, the oscillations became weakly synchronized and this synchronization was markedly enhanced in each case when the responses were evoked with a single long light bar that co-stimulated the two receptive fields. This suggests that synchronization depends on global features of the stimuli such as coherent motion and continuity, which are not reflected by the local responses alone.

The probability for the occurrence of phase locking depended both on the distance between recording sites and on the angular difference between preferred stimulus orientations (Table 1). There was no phase locking of the oscillatory responses when the electrodes were separated by 7–12 mm ( $n=16$ ). At intermediate distances of 2–7 mm, when the receptive fields of the recorded neurons were non-overlapping, phase locking occurred mainly between neuronal groups with similar orientation preferences. The same trend was observed for more closely spaced neurons (0.4–2.0 mm), which had overlapping receptive fields but in these cases phase locking was also observed for cells with different orientation preferences. Phase locking of oscillatory

responses typically occurred with a phase difference of 0 ms (32 out of 51) and the phase difference rarely exceeded  $\pm 3$  ms.

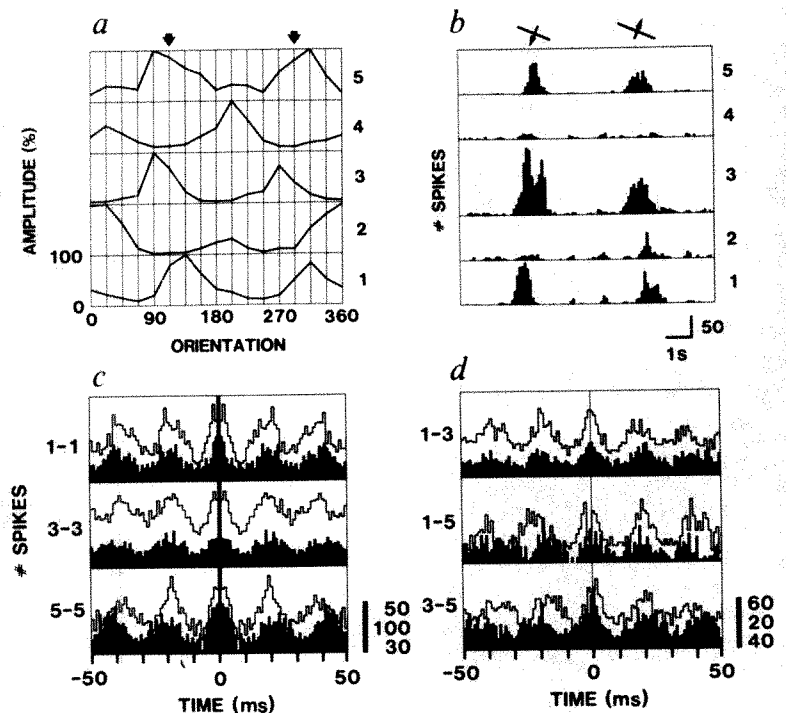

Our auto-correlation data confirm that the responses of a large fraction of cortical neurons are oscillatory and that these oscillations are synchronous for cells that are close enough together to be recorded with a single electrode<sup>1,2</sup>. Thus, we could take advantage of multi-unit recordings for the cross-correlation analysis, considerably increasing the number of events per unit time and allowing us to confine the analysis to short epochs. Correlations between the firing probabilities of neurons in the visual cortex have been described previously<sup>6–12</sup> and shown to be dependent on orientation preference<sup>6,9</sup> but only one study has provided evidence for oscillatory correlograms<sup>11</sup>. This relative lack of evidence for oscillatory responses in the cortex has several possible explanations. First, only a fraction of cortical neurons have oscillatory responses<sup>2</sup>; second, averaging procedures mask the oscillations because they are not phase-locked to the stimulus<sup>2</sup>; and third, previous studies may have excluded oscillatory activity because cross-correlograms of rhythmic responses were interpreted as misleading<sup>6,12</sup>.

The system of tangential intracortical connections<sup>13–19</sup>, or the reciprocal projections from other cortical areas<sup>20</sup> may provide the anatomical substrate for the synchronization of oscillatory responses between remote columns. Common input from sub-cortical structures can be excluded because collaterals of geniculate afferents do not span sufficiently large distances and do not have oscillatory responses in this frequency range<sup>1,2</sup>.

We propose that the synchronization of oscillatory responses in spatially separate regions of the cortex may be used to establish a transient relationship between common but spatially distributed features of a pattern<sup>21</sup>. Our data show that synchronization is sensitive to global features of stimuli such as continuity, similarity of orientation and coherency of motion. Synchronization may therefore serve as a mechanism for the extraction and representation of global and coherent features

FIG. 1 Orientation-specific intercolumnar synchronization of oscillatory neuronal responses in area 17 of an adult cat. *a*, Normalized orientation tuning curves of the neuronal responses recorded from five electrodes spaced 400  $\mu$ m apart and centred on the representation of the area centralis. Response amplitudes (ordinate) to stimuli of different orientations (abscissa) are expressed as a percentage of the maximum response for each electrode. The arrows indicate the stimulus orientation ( $112^\circ$ ) at which the responses were recorded in *b*, *c* and *d*. *b*, Post-stimulus time histograms recorded simultaneously from the same five electrodes at an orientation of  $112^\circ$ . Note the small difference in the latencies of the responses indicating overlapping but slightly offset receptive field locations. *c*, Auto-correlograms of the responses recorded at sites 1 (1–1), 3 (3–3) and 5 (5–5). *d*, Cross-correlograms computed for the three possible combinations (1–3, 1–5, 3–5) between responses recorded on electrodes 1, 3 and 5. Correlograms computed for the first direction of stimulus movement are displayed with unfilled bars with the exception of comparison 1–5 in *d*.

**METHODS.** Adult cats were prepared for acute physiological recordings from the visual cortex using standard procedures<sup>2</sup>. Anaesthesia was induced with a short acting anaesthetic (hexobarbital, 15 mg per kg or ketamine, 15 mg per kg) and then supplemented with a mixture of 30%  $O_2$ , 70%  $N_2O$  and 0.1–0.3% halothane. Multi-unit activity was recorded from an array of 4–6 closely spaced (300–500  $\mu$ m) platinum-iridium electrodes (25  $\mu$ m tip diameter) and an additional single electrode that was moved independently. The array was inserted in the vicinity of the representation of the area centralis. The single electrode was positioned anteriorly and advanced down the medial bank of area 17. All receptive field locations were within  $15^\circ$  of the area centralis. Spikes exceeding a threshold of twice the noise level were detected with a window discriminator and digitized with a resolution of 1 ms. All recordings used binocular stimulation after the receptive fields for the two eyes had been aligned using prisms. When neurons recorded from different electrodes had overlapping receptive fields but differing orientation preferen-

ces, we used a stimulus orientation that evoked a response at each site of at least half the maximal amplitude. Responses that did not meet this criterion and that did not overlap in time were excluded from the analysis. In the case of non-overlapping receptive fields we applied two independently controllable stimuli. For each trial the stimuli were moved across the receptive fields, at the preferred velocity, in both directions of movement perpendicular to the axis of orientation. Each trial lasted for 10 s and was repeated 10 times.

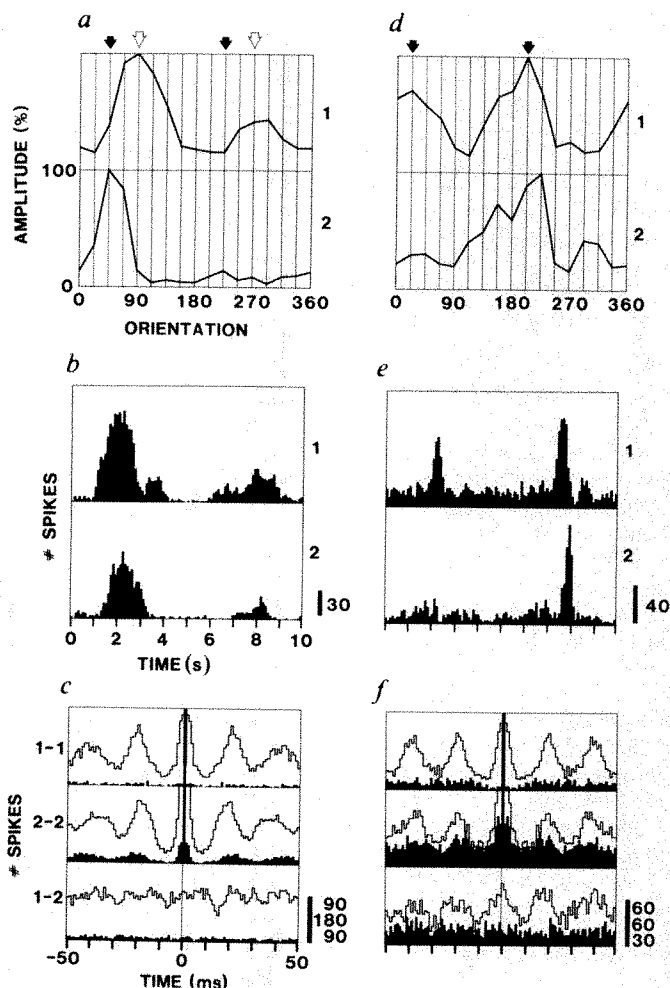

FIG. 2 Long-range inter-columnar synchronization of oscillatory responses depends on the similarity of orientation preference. *a*, Orientation tuning curves of multi-unit responses recorded at two sites (1 and 2) separated by 6 mm in area 17. The neurons had non-overlapping receptive fields and a clear difference in orientation preference of  $45^\circ$  (open and closed arrows). *b*, Post-stimulus time histograms of the responses recorded to stimulation of each receptive field at its own respective optimal orientation (open and closed arrows in *a*). *c*, Auto- (1-1, 2-2) and cross-correlograms (1-2) computed from the neuronal responses recorded from both electrodes revealed that oscillatory responses occurred at both sites but were not correlated. Unfilled bars are for the first direction of stimulus movement. *d*, Orientation tuning curves of multi-unit responses recorded from the same animal at two different cortical sites (1 and 2), separated by 7 mm. The neuronal responses at each site had similar orientation and directional preferences. *e*, Post-stimulus time-histograms of the activity recorded at each site in response to their optimal stimulus orientation of  $22^\circ$  (arrows in *d*). *f*, Auto- (1-1, 2-2) and cross-correlograms (1-2) computed from the neuronal responses recorded on the two electrodes demonstrate oscillatory responses at both sites which were correlated with zero phase difference. Unfilled bars are for the second direction of stimulus movement.

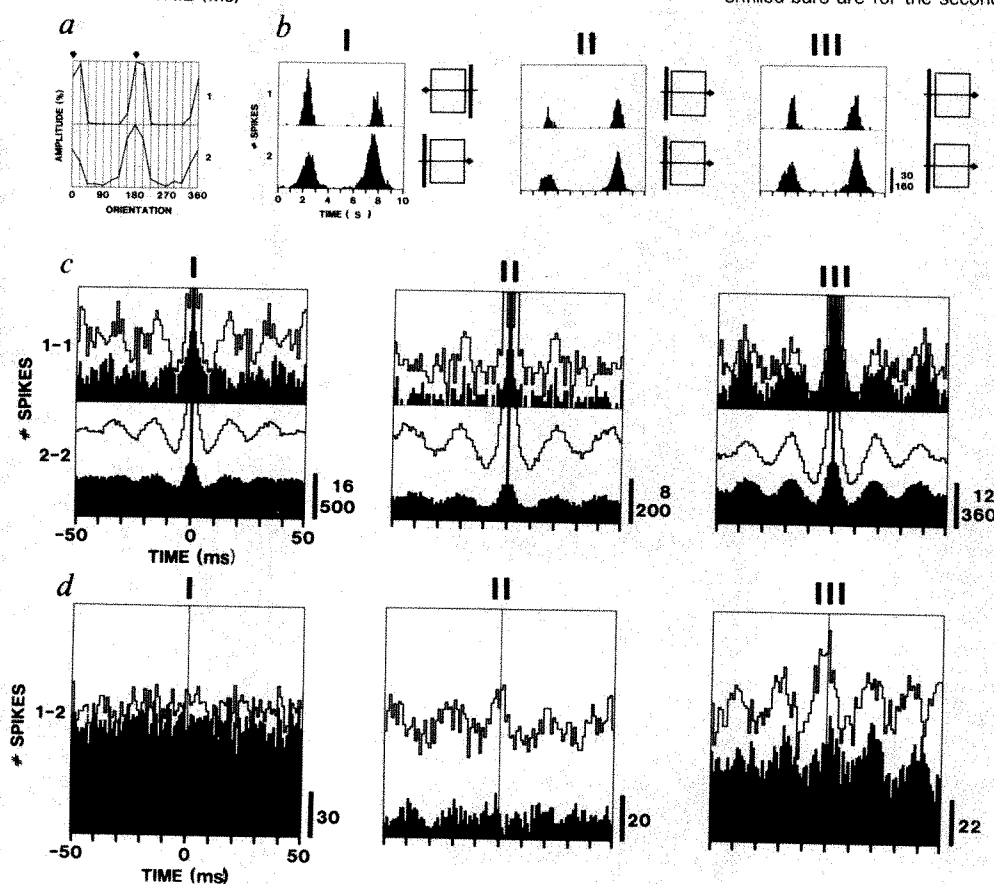

FIG. 3 Long-range oscillatory correlations reflect global stimulus properties. *a*, Orientation tuning curves of neuronal responses recorded from two electrodes (1, 2) separated by 7 mm show a preference for vertical light bars ( $0$  and  $180^\circ$ ) at both recording sites. *b*, Post-stimulus time-histograms of the neuronal responses recorded at each site for each of three different stimulus conditions: (I) two light bars moved in opposite directions; (II) two light bars moved in the same direction; and (III) one long light bar moved across both receptive fields. A schematic diagram of the receptive field locations and the stimulus configuration used is displayed to the right of each post-stimulus time histogram. *c*, *d*, Auto-correlograms (*c*, 1-1, 2-2) and cross-correlograms (*d*, 1-2) computed for the neuronal responses at both sites (1 and 2 in *a* and *b*) for each of the three stimulus conditions (I, II, III) displayed in *b*. For each pair of correlograms except the two displayed in *c* (I, 1-1) and *d* (I) the second direction of stimulus movement is shown with unfilled bars.

of a pattern. Such processes are crucial for the analysis of visual scenes and figure-ground segregation<sup>3,22-26</sup>. Synchronization of oscillatory responses may however also have a more general function in cortical processing because it is a powerful mechanism for establishing cell assemblies that are characterized by the phase and the frequency of their coherent oscillations. □

ACKNOWLEDGEMENTS. The results presented in this study were presented previously in abstract form (refs 27, 28).

## Transcripts of one of two *Drosophila* cyclin genes become localized in pole cells during embryogenesis

William G. F. Whitfield\*, Cayetano González\*, Ernesto Sánchez-Herrero†, & David M. Glover\*‡

CYCLINS, originally discovered in the eggs of marine invertebrates, are proteins which undergo dramatic cycles of synthesis followed by degradation at the metaphase-anaphase transition of cell division<sup>1-3</sup>. That they participate in the G<sub>2</sub>-M transition is supported by the fact that when synthetic cyclin messenger RNAs from clam and sea urchin are microinjected into the G<sub>2</sub>-arrested oocytes of *Xenopus*, they induce maturation<sup>2,4</sup>. The cyclin of fission yeast is the product of the *cdc13* gene, which is known to interact with *cdc2*, a gene required for the entry into mitosis<sup>5-10</sup>. We have cloned the genes that encode A-type and B-type cyclins from *Drosophila melanogaster* by virtue of their sequence similarity to oligonucleotides corresponding to conserved regions of the cyclin genes. We show that both genes encode abundant maternal mRNAs, but whereas the cyclin A mRNA is relatively uniformly distributed before cell formation, the cyclin B mRNA becomes localized to the developing pole cells. In larvae, cyclin A is expressed predominantly in brain and imaginal disks, whereas cyclin B transcripts are abundant in testes.

‡ To whom correspondence should be addressed.

FIG. 1. Developmental northern blots showing the transcripts detected by cDNA clones of cyclins A (a) or B (b). Poly (A<sup>+</sup>) RNA from the following developmental stages was analysed: lane 1, 0-2 h embryos; lane 2, 2-4 h embryos; lane 3, first instar larvae; lane 4, second instar larvae; lane 5, third instar larvae; lane 6, pupae; lane 7, adult males; lane 8, adult females. The autoradiograph shown was exposed for 15 h. The inset in the lower right-hand corner of each autoradiograph is an 80-h (cyclin A) or 60-h (cyclin B) exposure in which only the region containing RNA of ~2-kb from lanes f-h is displayed. Filters were re-probed with the *Drosophila ras* gene (*Dmras64B*) (ref. 16) as a control for uniform loading of RNA. The autoradiograph exposures indicated that the cyclin transcripts are 1-2 orders of magnitude more abundant than *ras* RNA in *Drosophila* embryos.

**METHODS.** An adult female *Drosophila* cDNA library in the bacteriophage vector  $\lambda$ gt10 was screened with a <sup>32</sup>P-labelled oligonucleotide mixture of sequence: AA(A/G)TA(T/C)GA(A/G)GA(A/G)ATTA(T/C)CC (probe 1). Hybridizations and washings were carried out as recommended by Wood et al.<sup>17</sup>. Duplicate filters were screened in parallel with a second oligonucleotide mixture: AT(T/C/A)(C/T)T(G/A)TGA(T/C)-TGG(T/C)TGT (probe 2). Positive plaques were purified by rescreening following the same protocol. The cDNAs fell into two classes: those that hybridized to both probes, and those that hybridized only to probe 1, cyclins A and B, respectively. We isolated three cyclin A cDNAs and four cyclin B cDNAs from ~5 × 10<sup>7</sup> recombinant phage in this library. On rescreening, a 0-2 h embryo cDNA library, we isolated both cyclin A and B clones at a frequency of 0.002. The amino-acid sequence corresponding to probe 1 can be recognized within the amino-acid sequence derived from the sequence of the cDNA clones and is shown below in relation to amino acids 249-261 of clam cyclin A<sup>2</sup>, and the corresponding regions of sea urchin cyclin<sup>4</sup> and *cdc13* (refs 7 and 8):

Clam A	L	A	A	K	Y	E	E	I	Y	P	P	D	V
Sea urchin	I	A	S	K	Y	E	E	M	Y	P	P	E	I
<i>cdc13</i>	I	A	S	K	Y	E	E	V	M	C	P	S	V
<i>Drosophila</i> A	I	A	A	K	Y	E	E	I	Y	P	P	E	V
<i>Drosophila</i> B	I	A	T	K	Y	E	E	L	F	P	P	A	I

The amino-acid sequence corresponding to probe 2 (in relation to amino-acids 196-208 of clam cyclin A) is as follows:

Clam A	M	R	C	I	L	V	D	W	L	V	E	V	S
Sea urchin	M	R	L	I	L	V	D	W	L	V	Q	V	H
<i>cdc13</i>	M	R	G	I	L	T	D	W	L	I	E	V	H
<i>Drosophila</i> A	M	R	S	I	L	I	D	W	L	V	E	V	S
<i>Drosophila</i> B	M	R	A	V	L	I	D	W	I	N	E	V	H

The cyclin A cDNAs hybridize *in situ* to salivary gland chromosomes at 68E, and thus correspond to a gene that has been independently cloned by Lehner and O'Farrell<sup>18</sup> and Y.-N. Jan (personal communication). The cyclin B gene hybridizes *in situ* to chromosome 2 at 59A. Northern blots using the cloned cDNAs as probes have been described previously<sup>19</sup>.

FIG. 2 *In situ* hybridization of a cyclin A cDNA probe to sections of embryos at various developmental stages. Bright-field and dark-field images are shown in the left and right panels respectively and embryos are oriented with the anterior pole to the left. Stages are according to Campos-Ortega and Hartenstein<sup>20</sup>. *a*, Early stage 2 embryo showing uniform distribution of signal. *b*, Late stage 2 embryo (nuclear cycle 7–8) showing uniform grain distribution. *c*, Early stage 4 embryo (nuclear cycle 10) in which the signal is becoming distributed toward the cortex. *d*, Late stage 4 embryo (division cycle 12). *e*, New cellular embryo (stage 6) with weaker signal throughout cellular region. *f*, Stage 8 embryo, mid-way through germ-band elongation showing extremely weak signal. *g*, Stage 11 embryo with fully elongated germ-band showing signal corresponding to zygotic transcripts. Hybridizations *in situ* were carried out according to refs 21 and 22, except that after labelling in a random oligonucleotide-priming reaction (20  $\mu$ l), the reactions were stopped by the addition of 1  $\mu$ l 0.5 M EDTA and 20  $\mu$ l 20 mM DTT. HCl (2  $\mu$ l, 5 M) was added and the incubation continued at 37 °C for 10 min, followed by the addition of NaOH (4  $\mu$ l, 5 M) and a further 20-min incubation. The reactions were neutralized with HCl (2  $\mu$ l, 5 M) and Tris-HCl (2  $\mu$ l, 2 M, pH 7.5).

FIG. 3 *In situ* hybridization of a cyclin B cDNA probe to sections of embryos at various developmental stages. Bright-field and dark-field images are shown in the left and right panels, respectively. *a*, Early stage 2 embryo showing uniform distribution of signal. *b*, Late stage 2 embryo (nuclear cycle 8) showing transcripts beginning to concentrate at the posterior pole. *c*, Late stage 3 embryo (nuclear cycle 9) in which pole cells have just formed and are prominently labelled. Remaining labelling is becoming distributed towards the cortex. *d*, Late stage 4 embryo (division cycle 12) with all the signal tightly distributed in the vicinity of the nuclei at the cortex. Pole-cell labelling is conspicuous. *e*, An embryo forming cells (stage 6) in which somatic signal has disappeared leaving grains only over pole cells. *f*, Stage 8 embryo, mid-way through germ-band elongation showing labelling exclusively over pole cells. *g*, Stage 11 embryo with fully elongated germ-band showing signal prominent pole cell labelling and onset of signal corresponding to zygotic transcripts.

FIG. 4 *a*, *In situ* hybridization of a cyclin A cDNA probe to a section of a third instar larva. The anterior of the larva is facing to the left, and bright-field and dark-field images are shown in the left and right panels, respectively. The strongest labelling is seen in distinct regions of the three lobes of the brain (b). The imaginal disks (d) show a much lower level of more uniform labelling just above background. *b*, *In situ* hybridization of a cyclin B probe to a section of a third instar larva. This part of the section shows labelling of the testes (t) close to the larval cuticle (c). The signal in the cuticle is likely to be non-specific as it has been observed with many other probes (E.S., unpublished observations; M. Akam, personal communication). Fixation and embedding of larvae was carried out according to ref. 23.

We have cloned complementary DNAs corresponding to transcripts encoding proteins which, on the basis of sequence comparisons with the cyclins of other organisms, we refer to as cyclins A and B (see Fig. 1 legend). Both these cDNAs detect 2.3-kilobase (kb) transcripts that are most abundant in pre-cellular embryos, and also occur at high levels in adult females, as would be expected for maternally provided mRNA (Fig. 1). A 2.5-kb zygotic transcript of the cyclin A gene appears after cell formation (Fig. 1a, lane b), and is present at low levels throughout subsequent development. Three cyclin A transcripts are detectable in pupae, only one of which is present in adult males at low levels (Fig. 1a, inset). The developmental distribution of cyclin B transcripts is similar, except that a zygotic transcript of a different size is not seen, and a male-specific transcript of 2 kb is readily detectable (Fig. 1b inset, lane g).

The abundance of these transcripts in early embryos is consistent with the expected role of cyclins in the 13 cycles of mitosis that occur in the first 2 hours of development<sup>11,12</sup>. We have examined the distribution of transcripts during embryogenesis by *in situ* hybridization and find that maternal message is initially distributed uniformly throughout the embryo (Fig. 2a, b). There seems to be a broad redistribution of the cyclin A transcripts towards the cortex during cycles 8 and 9 which continues in subsequent cycles. This could be either an active process in which mRNA migrates with mitotic apparatus and nuclei, or a more passive process by which transcripts are excluded from the interior region of the embryo occupied by the coalescing yolk (Fig. 2c-e), although other explanations, including the differential degradation of RNA, are possible. The abundance of the cyclin A transcripts falls dramatically following cell formation (Fig. 2f). At later stages, the cell cycle lengthens to 1-2 hours and two or three additional rounds of division occur in spatially restricted domains of the embryo (ref. 13, and V. Foe, personal communication). During these stages, zygotic transcripts appear (Fig. 2g) which, we surmise, correspond to the 2.5-kb RNA seen in the northern blots (Fig. 1).

Maternal cyclin B transcripts are first found uniformly throughout the embryo (Fig. 3a). They then undergo a dramatic redistribution such that by cycles 8-9, when nuclei are migrating to the cortex, cyclin B transcripts are becoming concentrated at the posterior pole (Fig. 3b). It is also possible that this represents *de novo* transcription in the nuclei reaching the posterior pole.

These nuclei undergo cellularization several cycles before the majority to form pole cells (Fig. 3c). As the somatic nuclei complete their syncytial mitotic cycles, cyclin B transcripts show a clear association with the cortex near nuclei (Fig. 3d). These cortical transcripts disappear abruptly during cell formation of somatic nuclei (Fig. 3e). Transcripts either persist or continue to be produced in the pole cells as they move dorsally and anteriorly in germ-band elongation (Fig. 3f). Some zygotic cyclin B transcription seems to ensue in the soma in later embryos, although the predominant labelling is still detected in pole cells (Fig. 3g). The redistribution of cyclin B mRNA in the syncytial embryo suggests that these transcripts contain localization signals that allow them to remain close to dividing somatic nuclei and the developing pole cells. Other maternal mRNAs are known to have specific distributions in early embryos: the graded distribution of *bicoid* mRNA, with its maximum concentration at the anterior pole of the *Drosophila* embryo, for example, requires a specific sequence present at its 3' untranslated end<sup>14</sup>.

After the hatching of the embryo, most of ensuing larval development involves cell growth and polytenization in the absence of cell division. The exceptions are the imaginal tissues that must proliferate to form adult structures, neuroblasts within the larval brain, and the mitotic lineages of the germ cells. We find that expression of cyclin A, but not cyclin B, is readily detectable in the periphery of the three brain lobes, and, at a lower level, in imaginal disks of third instar larvae (Fig. 4a). Conversely, cyclin B transcripts predominate in the larval testes (Fig. 4b), and presumably correspond to the prominent male-specific 2-kb cyclin B RNA, detected by northern blotting (Fig. 1).

Several aspects of germ-cell proliferation are significantly different from mitotic cell division in somatic tissues. In the imaginal discs, for example, there is a target cell number that may be controlled by cell-cell contacts of a certain pattern<sup>15</sup>. By contrast, cell division continues in the stem cells of the testes and ovary throughout the life of the organism to produce daughter stem cells and primary gonial cells. In addition, the premeiotic mitoses of the gonial cells in both male and female are accompanied by incomplete cytokinesis to produce groups of cells that share cytoplasm connected by canals. In spermatogenesis, the gonial cells undergo 4 mitotic and 2 meiotic

divisions within cysts to produce 64 spermatids. In oogenesis a cyst of 16 interconnected cells develops, of which 14 will undergo polyploidization to form the nurse cells and one will become the oocyte, *per se*, and undergo meiosis. One might speculate that there is a need for a specific cyclin either to maintain stem-cell proliferation (to provide for the peculiarities of what are essentially syncytial divisions in the gonial cysts) or to mediate the ultimate transition between mitotic and meiotic divisions. □

## A diacylglycerol analogue reduces neuronal calcium currents independently of protein kinase C activation

Philip Hockberger\*, Mauro Toselli, Dieter Swandulla† & H. Dieter Lux

Department of Neurophysiology, Max Planck Institute for Psychiatry, D-8033 Martinsried-Planegg, FRG

DIACYLGLYCEROL analogues (for example 1,2-oleoylacetyl-glycerol, OAG) and phorbol esters are activators of protein kinase C, and have been widely used to study the function of this enzyme in both intact cells and cell-free preparations<sup>1,2</sup>. Electrophysiological studies have shown that these activators can either depress<sup>3–6</sup> or increase  $\text{Ca}^{2+}$  currents<sup>7–9</sup>, or decrease  $\text{K}^{+}$  currents<sup>10,11</sup> when applied outside the cell. It has been assumed that these effects are mediated by protein kinase C activation. Here we report that micromolar levels of OAG and phorbol esters depress  $\text{Ca}^{2+}$  currents in chick sensory neurons independently of their effect as activators of protein kinase C. The depression of the  $\text{Ca}^{2+}$  current is rapid and is unaffected by intracellular application of the protein kinase C inhibitors staurosporin, sphingosine and H-7<sup>12</sup>. Furthermore, the activators were ineffective when applied intracellularly, indicating that their site of action is on the outside of the membrane.

Intracellular patch-clamp recordings were performed in acutely isolated dorsal root ganglion cells from 10–13-day-old

chick embryos<sup>13,14</sup>. Figure 1a shows the change in action potential waveform induced by OAG<sup>15</sup> (5  $\mu\text{M}$ ), which was delivered by pressure application through a micropipette positioned 10–20  $\mu\text{m}$  from the cell. OAG reversibly depressed the amplitude of the spike and slightly prolonged its duration.

Under voltage-clamp, OAG reduced the total membrane current (see Fig. 1b), but isolated voltage-dependent  $\text{Na}^{+}$  currents, and also  $\text{K}^{+}$  currents<sup>3</sup>, were unaffected. A large, reversible decrease in the amplitude of isolated  $\text{Ca}^{2+}$  currents was recorded (Fig. 1c; see also ref. 3). A subsequent reduction of a  $\text{Ca}^{2+}$ -activated  $\text{K}^{+}$  conductance could account for the decrease in the outward current shown in Fig. 1b.

$\text{Ca}^{2+}$  currents recorded under the conditions of Fig. 1c typi-

FIG. 1 Whole-cell recordings from chick dorsal root ganglion neurons before (c, control), during and after (r, recovery) 5-s exposures to 5  $\mu\text{M}$  OAG. a, OAG application reduced the action potential amplitude and delayed repolarization by several ms (resting potential  $-55$  mV). Recovery was 13 s after OAG application. Small hyperpolarizations (5–10 mV) were due to a non specific effect of the pressure application and were also observed when external saline was applied. b, Under voltage-clamp, both inward and outward currents were reversibly depressed by OAG (same cell as in a). c, OAG application reversibly reduced  $\text{Ca}^{2+}$  currents. Activating steps were from  $-50$  (b) and  $-80$  mV (c) to 0 mV.

METHODS. Electrode resistances were 3–5 M $\Omega$ . Normal external salines contained (in mM): NaCl, 130; KCl, 5.4;  $\text{MgCl}_2$ , 2;  $\text{CaCl}_2$ , 2; HEPES 10 (pH 7.3). The internal electrode solution contained (in mM) potassium aspartate, 130; EGTA 10;  $\text{CaCl}_2$ , 1;  $\text{Mg-ATP}$ , 2; HEPES, 10 (pH 7.3).  $\text{Ca}^{2+}$  currents were recorded in isolation in external saline containing (in mM): choline chloride, 120;  $\text{CaCl}_2$ , 5;  $\text{MgCl}_2$ , 2; HEPES, 10 (pH 7.3) and internal solution containing (in mM) CsCl, 100; TEA-Cl, 20;  $\text{Mg-ATP}$ , 2; EGTA, 10;  $\text{CaCl}_2$ , 0.1; HEPES, 40 (pH 7.3). Sodium currents were analysed using external saline containing (in mM) NaCl, 120;  $\text{NiCl}_2$ , 5;  $\text{MgCl}_2$ , 2; HEPES, 10 (pH 7.3). Potassium currents were analysed using external saline containing (in mM) choline chloride, 150;  $\text{NiCl}_2$ , 5;  $\text{MgCl}_2$ , 2; HEPES, 10 (pH 7.3) and internal electrode solution containing (in mM) potassium aspartate, 130;  $\text{MgCl}_2$ , 2; EGTA, 10; HEPES, 10 (pH 7.3). The temperature was 22  $^{\circ}\text{C}$ . Stock solutions of OAG (50 mM, Sigma) were prepared in chloroform and diluted in external saline. OAG did not immediately dissolve in the chloroform, as solutions tested the same day had no effect. Stock solutions were then stored for 3–4 weeks at 4  $^{\circ}\text{C}$  after which they did depress  $\text{Ca}^{2+}$  currents. Stock solutions of  $\text{dCa}_8$  (50 mM, Sigma), sphingosine (200 mM, Sigma) and H-7 (50 mM, Sigma) were prepared in chloroform and stock solutions of staurosporin (1 mM, Boehringer) were prepared in dimethylsulphoxide. Phorbol esters (1–11 mM, Sigma) were dissolved in ethanol. Stock solutions were stored at 4  $^{\circ}\text{C}$ . Sonification improved the solubility of the compounds.

FIG. 2 Rate of reduction of the  $\text{Ca}^{2+}$  current during application of 5  $\mu\text{M}$  OAG ( $n=5$ ) and 10  $\mu\text{M}$  TPA ( $n=2$ ). The measurements were made using a delivery system that exchanges the solution surrounding the cell in about 50 ms (ref. 22). The difference between peak currents recorded after prolonged washout and during drug applications of various duration was normalized to the difference between peak currents recorded after washout and after prolonged (20 s) drug application.

cally inactivated with a time constant of several hundred ms, as described for high-threshold (L-type)  $\text{Ca}^{2+}$  currents<sup>16-19</sup>. During OAG application, the reduced  $\text{Ca}^{2+}$  current inactivated faster when 0.1% chloroform was used as a solvent but not with lower concentrations. Recovery was slower than that of the peak current. Similar results were obtained with another diacylglycerol analogue, *sn*-1,2-dioctanoylglycerol ( $\text{diC}_8$ )<sup>20</sup>, and the three phorbol esters, *O*-tetradecanoylphorbol-13-acetate (TPA, phorbol myristyl acetate), phorbol-12,13-diacetate (PDA) and 4- $\alpha$ -phorbol-12,13-didecanoate (4- $\alpha$ -PDD).

We did not record shifts in the current-voltage relationship or changes in the cell leakage conductance during application of these agents (see also refs 3-5). Steps from -80 mV to 0 mV activated both high and low threshold (T-type)  $\text{Ca}^{2+}$  currents<sup>16-19</sup>. We found that the T-type current, which constitutes about 15% of the total  $\text{Ca}^{2+}$  current, was also transiently and reversibly blocked by OAG; similar observations have been made in GH3 cells<sup>5</sup>.

Table 1 (top) summarizes our results with diacylglycerol analogues and phorbol esters. Phorbol esters and  $\text{diC}_8$  were less effective than OAG even at 10-fold higher concentrations. Control solutions of either glycerol or the solvents had no significant effect on the peak  $\text{Ca}^{2+}$  current. Interestingly, 4- $\alpha$ -PDD, which does not activate protein kinase C<sup>21</sup>, was as effective as the other phorbol esters at depressing  $\text{Ca}^{2+}$  currents.

TABLE 1 Effects of activators and inhibitors of protein kinase C

External pipette	Internal pipette	Per cent decrease $I_{\text{peak}}$ (mean $\pm$ s.d.)	<i>n</i>
0.5 $\mu\text{M}$ OAG	—	2 $\pm$ 2	7

200 $\mu\text{M}$ sphingosine	—	32 $\pm$ 8	3
50 $\mu\text{M}$ H-7	—	31 $\pm$ 10	5

All agents were delivered through micropipettes for either 5 s externally or for a minimum of 10 min internally. Chloroform was the solvent for OAG and  $\text{diC}_8$ , and ethanol was used to dissolve the phorbol esters (see text for details).  $I_{\text{peak}}$ , peak voltage-dependent  $\text{Ca}^{2+}$  current; *n*, number of cells examined.

We measured the onset of  $\text{Ca}^{2+}$  current reduction by OAG and TPA using a rapid delivery system<sup>22</sup> (Fig. 2). Inhibition developed in less than 50 ms and was half-maximal by 200 ms. The offset of the response was similarly fast, indicating that the action was probably limited by diffusion. These results indicate that the drugs may be acting on the outside of the membrane, and not through an enzymatic pathway on the inner membrane.

To examine this possibility more directly, we tested whether the activators could depress  $\text{Ca}^{2+}$  currents after inhibition of protein kinase C. Table 1 (middle) summarizes our results from cells perfused internally with either staurosporin<sup>23</sup> sphingosine<sup>24,25</sup> or H-7<sup>26</sup>. We used H-7 and staurosporin at concentrations that were 10 and 100 times their respective inhibition constants ( $K_i$ ) (obtained from *in vitro* studies<sup>23,25</sup>). As the  $K_i$  for sphingosine is unknown, we used concentrations of 50  $\mu\text{M}$  and 200  $\mu\text{M}$ , the latter reducing protein kinase C activity by 90% in several cell types<sup>24,25</sup>. The inhibitors had no significant effect on the OAG responses. All values were obtained a minimum of 10 min after the start of cell perfusion and, in several cells, after 30 min. With 2 mM ATP and 40 mM HEPES buffer in the internal pipette, there was no evidence for rundown of the  $\text{Ca}^{2+}$  current before 30 min (see also refs 27 and 28). Similarly, internal H-7 (50  $\mu\text{M}$ ) had no effect on the  $\text{diC}_8$  or phorbol ester responses (Table 1, centre). Sphingosine and H-7, applied at the same concentration to the outside of cells, quickly and reversibly reduced the  $\text{Ca}^{2+}$  current (Table 1, bottom).

In a different approach, we tested whether OAG was effective if applied intracellularly. For these experiments, we used two

FIG. 3 Current and voltage measurements using a three-electrode recording arrangement to compare the effects of OAG applied inside (50  $\mu\text{M}$ ) and outside (5  $\mu\text{M}$ ) to the same cell. *a*, Control record (*c*) of the  $\text{Ca}^{2+}$  current recorded with the first patch electrode during a voltage step from -80 mV to 0 mV. *b*, 10 min after the whole-cell configuration was established with the second (OAG) patch electrode, the  $\text{Ca}^{2+}$  current was unchanged (OAG in). External application of OAG through a third microelectrode was still effective at blocking the  $\text{Ca}^{2+}$  current (OAG out) however. Membrane voltage with the second patch electrode ( $V_2$ ) was recorded in the current-clamp mode. The slowly decaying tail currents in the control and internal OAG records may indicate inadequate clamping on repolarization as they were not present under better recording conditions<sup>13</sup>.

patch pipettes, one filled with control internal saline and the other with internal saline plus 50  $\mu$ M OAG (Fig. 3). This high concentration was necessary because OAG is rapidly metabolized<sup>15</sup>. In all seven experiments we found no change in the  $\text{Ca}^{2+}$  current during intracellular OAG application even after 25 min (average duration was 15 min). In five cases, we applied OAG externally from a third electrode and recorded the usual OAG decrease of the current (Fig. 3b). In three similar experiments using H-7 (50  $\mu$ M) in the second electrode instead of OAG, there was no measurable effect on the  $\text{Ca}^{2+}$  current. Because micromolar  $\text{Ca}^{2+}$  concentrations are necessary for protein kinase C activity in the absence of diacylglycerol analogues<sup>1</sup>, total  $\text{CaCl}_2$  concentration in the internal solution was raised for these experiments from 1 mM to 9.1 mM to increase the free  $\text{Ca}^{2+}$  concentration from 0.1  $\mu$ M to 1  $\mu$ M.

We conclude that OAG and H-7 act on the outside of dorsal root ganglion neurons to depress the  $\text{Ca}^{2+}$  current. We suspect that the other agents tested act in the same way, although our evidence is less direct. At the inhibitor concentrations used, both protein kinase C and cyclic AMP-dependent and cyclic GMP-dependent protein kinases should have been completely inhibited, indicating that the functioning of  $\text{Ca}^{2+}$  channels in dorsal root ganglion neurons does not depend on these protein kinases. This might not be the case in all cell types<sup>29-31</sup>.

The demonstration of external action of activators and inhibitors of protein kinase C is reminiscent of recent results for forskolin, an adenyl cyclase activator. Several studies have presented evidence that forskolin may affect  $\text{Ca}^{2+}$  currents<sup>32</sup> and  $\text{K}^{+}$  currents<sup>33-36</sup> independently of cyclase activity. Like forskolin, OAG and H-7 did not affect the  $\text{Ca}^{2+}$  current when applied intracellularly. These molecules apparently possess little affinity for the  $\text{Ca}^{2+}$  channel on the inner side of the membrane, although the fast on-kinetics suggest a high-affinity external binding site. Direct antagonistic effects on  $\text{Ca}^{2+}$  channels must be considered when applying these agents extracellularly to study events involving protein kinase C. □

## Linkage of a prion protein missense variant to Gerstmann-Sträussler syndrome

GERSTMANN-Sträussler syndrome is a rare familial neurodegenerative condition that is vertically transmitted, in an apparently autosomal dominant way<sup>1</sup>. It can also be horizontally transmitted to non-human primates and rodents through intracerebral inoculation of brain homogenates from patients with the disease<sup>2-8</sup>. The exact incidence of the syndrome is unknown but is estimated to be between one and ten per hundred million. Patients initially suffer from ataxia or dementia and deteriorate until they die, in one to ten years. Protease-resistant prion protein (PrP) and PrP-immunoreactive amyloid plaques with characteristic morphology accumulate in the brains of these patients<sup>9-11</sup>. Current diagnostic criteria for Gerstmann-Sträussler syndrome incorporate clinical and neuropathological features, as animal transmission studies can be unreliable<sup>8,12</sup>. PrP is implicated in the pathogenesis and transmission of the condition and in scrapie, an equivalent animal disease<sup>13-17</sup>. It was discovered by enriching scrapie-infected hamster brain fractions for infectivity<sup>18,19</sup>. Because there is compelling evidence that the scrapie isoform of PrP is a necessary component of the infectious particle<sup>15,16</sup>, it seemed possible that the PrP gene on the short arm of human chromosome 20 (ref. 20) in Gerstmann-Sträussler syndrome might be abnormal. We show

FIG. 1 Organization of PrP alleles in ataxic GSS. Top, Wild-type PrP allele (a); bottom, variant PrP allele found in ataxic GSS (A). The open reading frame is indicated by an open box, the mRNA untranslated region by a narrower box and the intron by a solid black line. Restriction sites: P, *PvuII*; D, *DdeI*. Sa indicates a putative 3' splice site (splice acceptor). Asterisks indicate locations of polymorphic restriction sites; broken vertical lines indicate locations of polymorphic codons. Brackets indicate locations of synthetic primers K (5'-AAGAATTCTCTGACATTCCTCTTCA-3') and H (5'-AAGGATCCCTCAA-GCTGGAAAAAG-3') used in cyclic thermal DNA amplifications. The K oligonucleotide is based on unpublished sequence data of the intron in the human PrP gene; a partial sequence of the intron 5' to the open reading frame of the A allele and including the initiation codon is: 5'-CATTATGCAGAAACATTT-AGTAAATCAACATAAATATGGAACCTCTGACATTCCTCTTCTTTCAGAGCA-GTCATTATG-3'. This data was obtained during sequencing of the two PrP alleles in patient JJ. H and K oligonucleotides were constructed to include 5'-*Bam*HI and *Eco*RI linkers, respectively.

here that PrP codon 102 is linked to the putative gene for the syndrome in two pedigrees, providing the best evidence to date that this familial condition is inherited despite also being infectious, and that substitution of leucine for proline at PrP codon 102 may lead to the development of Gerstmann-Sträussler syndrome.

We sequenced both alleles of the PrP open reading frame in J.J., a patient with Gerstmann-Sträussler syndrome (GSS) from a US pedigree (see III-a, Fig. 2a). Five recombinant bacteriophage containing the PrP open reading frame were recovered from a  $\lambda$ -EMBL-3 library constructed from the patient's peripheral leukocyte DNA and screened with a human PrP cDNA<sup>21</sup>. There are two PrP alleles, which can easily be distinguished in genomic DNA and recombinant clones because one allele differs from the other by the absence of a *PvuII* restriction site located in the PrP open reading frame. This polymorphism has been reported previously; the *PvuII* site is present in 90% of the population<sup>22</sup>. We found that the *PvuII* site was abolished by a 'silent' adenine to guanine substitution in the third position of alanine codon 117. One of the five clones lacked this *PvuII* site. In the same clone, a cytosine to thymine substitution in the second position of codon 102 resulted in a proline to leucine change, creating a *DdeI* restriction site (Fig. 1). No other variations between the two alleles were found. The other allele was identical to another published PrP gene sequence<sup>21</sup> and is presumably the wild-type allele.

To determine whether the leucine substitution at codon 102 was present in other individuals we used either Southern blotting analysis with *DdeI*-digested genomic DNA, or restriction digests of genomic DNA amplified by the polymerase chain reaction (Fig. 1) visualized directly with ethidium bromide (see Fig. 3). We found the leucine substitution in the two other individuals (J.B. and J.C.) that we examined with ataxic GSS, both of whom are members of an extensive British pedigree (see III-20 and

IV-2, Fig. 2, lower pedigree). The leucine substitution was not present in eight unaffected relatives of J.J., J.B., or J.C. who are beyond the age for being at risk for the disease (Figs 2 and 3). Nor was it found in 15 patients with other forms of inherited or sporadic prion diseases, or in 100 unrelated, normal Caucasian individuals of the same ethnic background as the British and US pedigrees.

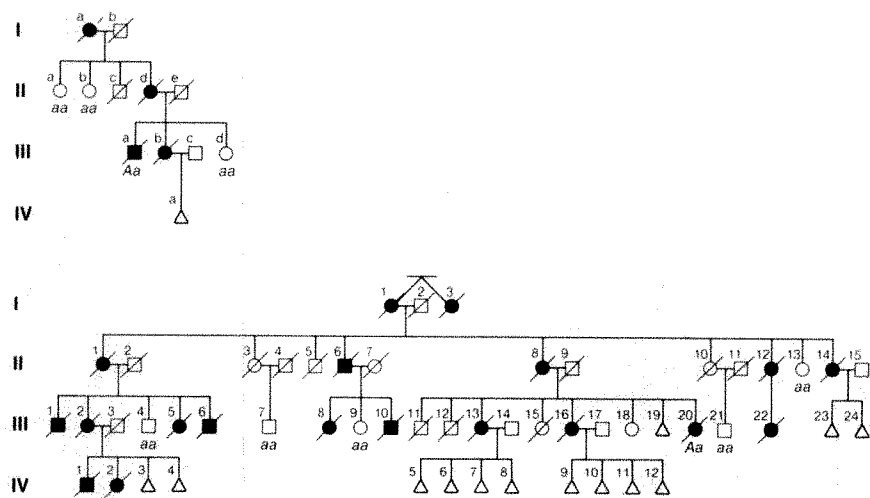

The family data were analysed for genetic linkage using the LIPED computer program<sup>23</sup>. We assumed that the disease followed a dominant mode of inheritance with age-dependant penetrance, where penetrance was assumed to rise linearly from 0 at age 21 to 100% at age 40 in the US family and from 0 at age 38 to 100% at age 66 in the British family. Under these conditions, the log likelihood ratio (lod score) is lowered by asymptomatic individuals with the leucine substitution who are older than the minimum age of onset. As the disease is known to be extremely rare, a population frequency of  $q=1$  in 10,000,000 was assumed for the disease gene, corresponding to a disease prevalence of 2 in 10,000,000 among older individuals beyond the age at risk. Even for values of  $q$  as high as 0.0001, the results in Table 1 are unaltered.

The population frequency of the leucine substitution,  $p$ , is crucial for the linkage analysis as many married-in spouses are of unknown genotype at this marker locus. When the substitution is rare, it is probably inherited from one of the founding members in each pedigree who also passed the disease gene to his or her offspring. None of a random sample of 100 Caucasian individuals carried the substitution (no substitution in 200 alleles) so that the 95% confidence interval for the allele frequency,  $p$ , extends from 0 to  $1 - 0.05^{0.005} = 0.015$  and the 99% confidence interval for  $p$  ranges from 0 to 0.023.

The results shown in Table 1 demonstrate significant tight linkage between the disease and the marker locus, the maximum

FIG. 2 Pedigrees of two families with ataxic GSS. Circles, females; squares, males; triangles, males or females; a black symbol indicates that an individual is affected with GSS; a slashed symbol that an individual is deceased. The clinical and pathological aspects of these pedigrees will be described in detail elsewhere. On the basis of the predicted amino-acid sequence, *a* indicates a proline at codon 102 and *A* indicates a leucine at that codon. Because of their predictive nature, the alleles for individuals at risk for illness (triangles) are not shown in order to protect the confidentiality of these people. The distribution of the candidate alleles in the at-risk group was found to be in accordance with that expected for an autosomal dominant trait. Detailed information of allelic assignments on which the lod score calculations are based will be made available to investigators for scientific purposes only but in strict confidence.

Top, Pedigree of US family with ataxic GSS. This is a previously unreported pedigree. IV-a (age 23) developed leg pains and gait instability in 1988, but is scored as an individual at risk for illness in the absence of a more definitive diagnosis. The diagnosis of GSS was confirmed in III-a and III-b by positive staining of amyloid plaques with anti-PrP antibodies. The known ages (in years) of onset for affected individuals are: I-a, 40; II-d, 22; III-a, 39; and III-b, 29. Hamsters which received intracerebral inoculations of a 10% brain homogenate from III-a are still asymptomatic after 500 days. Both alleles of the PrP open reading frame were sequenced in the index case, III-a, using a combination of methods described by Maxam and Gilbert<sup>35</sup> and Biggin and co-workers<sup>36</sup>. Bottom, Pedigree of a British family with GSS. This pedigree has been extensively analysed, both clinically and pathologically<sup>4,6,37,38</sup>. PrP-positive plaques were demonstrated in III-20 and IV-2. The known ages (in years) of onset for affected individuals are: II-6, 52; II-8, 46; II-12, 66; III-1, 65; III-2, 54; III-5, 57; III-6, 60; III-8, 48; III-10, 42; III-13, 51; III-16, 39; III-20, 48; III-22, 59; and IV-2, 40. The ages of individuals at risk for illness are: III-19, 58; III-23, 58; III-24, 51; IV-3, 53; IV-4, 51; IV-5, 38; IV-6, 34; IV-7, 32; IV-8, 30; IV-9, 40; IV-10, 39; IV-11, 35; and IV-12, 34. Hamsters which received intracerebral inoculations of 10% brain homogenates from III-20 and IV-2

developed neurological disease at  $317 \pm 21.8$  ( $n=5$ ) and  $300 \pm 11.2$  ( $n=8$ ) days, respectively, and died at  $327 \pm 19.6$  and  $305 \pm 11.5$  days, respectively. Transmission of brain homogenates from IV-2 (ref. 6) and III-10 (ref. 4) to monkeys has been reported previously.

**METHODS.** Relevant family members were examined by a neurologist and blood samples were obtained. DNA was extracted from the buffy coat in all instances except IV-2 for which only frozen brain was available. DNA from III-20 and IV-2 was extracted from freshly frozen tissue. We also extracted DNA using a previously published method<sup>34</sup> from formalin-fixed brains from several other affected members of these two pedigrees, for example III-b, III-10 and III-22, and from a single patient from a third pedigree. We found discrepancies between data obtained from matched control samples of DNA from fresh and formalin-fixed tissue, however. Therefore, even though the mutant *DdeI* site was present in each of these four additional GSS cases, we excluded these data from our analysis. Codon 102 of the PrP open reading frame was determined by digestion with *DdeI* of DNA amplified between the primers described in Fig. 1.

lod score being equal to  $Z = 3.26$  at a recombination fraction of  $\Theta = 0$  ( $p = 0.01$ ). The commonly used approximate confidence interval for  $\Theta$  extends from 0 to 0.14, which is the value of  $\Theta$  with a lod score of  $Z = 1$ .

The US and British pedigrees seem to be lineally distinct both on the basis of currently available genealogical inquiries and comparison of the restriction map in the PrP open reading frame. The *PvuII* polymorphism at codon 117 is present in the US family but not in the British family. Although more extensive genealogical investigation could conceivably reveal common ancestry between these two pedigrees, at present it seems more likely that the mutation causing the leucine substitutions at codon 102 arose independently in the two pedigrees. This base substitution may have involved deamination of a methylated cytosine situated 5' to guanine and therefore represents a relatively common mutation in human DNA<sup>24</sup>. The proline at codon 102 seems to be highly conserved as all rodent PrP genes sequenced so far also encode a proline at the equivalent codon<sup>14,24-29</sup>.

The codon 102 proline→leucine substitution is possibly located within a surface loop which is nine residues from a putative transmembrane  $\alpha$ -helix<sup>30</sup>. It would therefore be unlikely to exert a significant effect on the secondary structure of PrP. The biological consequences of single amino-acid substitutions that do not perturb secondary structure can nevertheless be profound, as in certain haemoglobinopathies and neoplasias<sup>31-33</sup>.

We believe that, on the basis of clinical and pathological criteria, GSS can be classified into three forms: an ataxic form, for which the leucine substitution seems to be characteristic; a dementing form; and a dementing form that is accompanied by pathological quantities of neurofibrillary tangles. When familial Creutzfeldt-Jakob disease is included, at least four forms of human inherited prion diseases can be deciphered<sup>40</sup>. A fuller

description of this proposed classification will be published elsewhere.

The linkage between the PrP gene and GSS in two pedigrees establishes, for the first time, that GSS is a genetic disorder. Our observations parallel earlier studies where the murine PrP gene was found to be linked to susceptibility (that is, length of the incubation time) for experimental scrapie after inoculation with prions<sup>13</sup>. Moreover, our discovery of a unique PrP gene amino-acid substitution on the same chromosome that carries the GSS locus in two pedigrees also resembles earlier studies in which substitutions of two amino-acid residues at PrP codons 108 and 189 correlate with short and long incubation times in experimental scrapie studies in mice<sup>14</sup>. If the leucine substitution at codon 102 arose independently in our two pedigrees, then we believe it could represent more than a linked genetic marker and might itself provoke the development of GSS. Although the composition of the GSS prion has not been determined directly, it seems likely, by analogy with results from experimental scrapie studies in rodents, that the GSS prion is composed largely, if not entirely, of an abnormal isoform of human PrP. The striking and specific correlation between the leucine substitution and the ataxic form of GSS leads us to speculate that other specific mutations in PrP may correlate with the other forms of inherited prion diseases. □

FIG. 3 Restriction patterns of twelve informative cases from the families with ataxic GSS shown in Fig. 2.

**METHODS.** Genomic DNA extracted from peripheral leukocytes was amplified using the *Thermus aquaticus* (Taq) heat-stable DNA polymerase as previously described<sup>39</sup>. Amplification reactions used 1–2  $\mu$ g of DNA in a 100  $\mu$ l solution containing 1  $\mu$ M each of primer KH10 and KH11 and 2.5 units Taq polymerase in the reaction buffer provided by the supplier (Perkin-Elmer-Cetus). The samples were overlaid with two drops of mineral oil to prevent evaporation and were subjected to 35 cycles of amplification. The cycling reaction was performed in a programmable heat block (DNA Thermal Cycler, PECL) set to incubate the samples at 94 °C for 90 s (to denature the DNA), at 55 °C for 60 s (to anneal the primers), and at 72 °C for 3 min (to extend the annealed primers). The reaction product (30–60  $\mu$ l) was fractionated on a preparative 1.5% agarose gel from which an 864-base pair fragment was excised and purified using GeneClean (Bio 101). The excised fragment (30 mg) was digested to completion with 5 units *DdeI* in a volume of 12  $\mu$ l using the buffer recommended by the supplier. The DNA was fractionated on a 3%:1% NuSieve-SeaKem agarose gel (FMC Corp.) containing ethidium bromide (0.5  $\mu$ g ml<sup>-1</sup>) in 40 mM Tris-acetate, 2 mM EDTA buffer. *HaeIII*-digested  $\phi$ X 174 DNA (250 ng) was loaded as a size marker.

**ACKNOWLEDGEMENTS.** We thank R. Lofthouse for technical help, G. W. Roberts for assistance in preliminary experiments while holding a Ciba Foundation scholarship and R. M. Ridley for help in collecting the extended pedigree. We are grateful to K. Boylan for normal DNA and GSS blood, B. Miller for referring the American pedigree, S. DeArmond for pathologic studies, R. Fletterick for helpful advice, and L. Gallagher for editorial assistance. This work was supported by research and fellowship grants from the NIH, State of California Department of Health Services, UK Medical Research Council and a Senator Jacob Javits Center of Excellence in Neuroscience as well as by gifts from Sherman Fairchild Foundation, RJR/Nabisco, Inc., National Medical Enterprises, Inc., and the W. M. Keck Foundation. This investigation was conducted under the guidelines of the Northwick Park Hospital Ethical Committee and the Committee on Human Research at UCSF.

## Polymorphism in the $\alpha_3$ domain of HLA-A molecules affects binding to CD8

**CYTOTOXIC T lymphocytes (CTL) expressing the CD8 glycoprotein recognize peptide antigens presented by class I major histocompatibility complex (MHC) molecules<sup>1,2</sup>. This correlation and the absence of CD8 polymorphism led to the hypothesis that CD8 binds to a conserved site of class I MHC molecules. Using a cell–cell binding assay we previously demonstrated specific interaction between human class I MHC (HLA-A,B,C) molecules and CD8 (ref. 3). Subsequent analysis of the products of 17 HLA-A,B alleles revealed a natural polymorphism for CD8 binding in the human population. Two molecules, HLA-Aw68.1 and HLA-Aw68.2, which do not bind CD8, have a valine residue at position 245 whereas all other HLA-A,B,C molecules have alanine. Site-directed mutagenesis shows that this single substitution in the  $\alpha_3$  domain is responsible for the CD8 binding phenotype and also affects recognition by alloreactive and influenza-specific CTL. Our results indicate that CD8 binds to the  $\alpha_3$  domain of class I MHC molecules.**

Various class I MHC alleles were transfected into the HLA-A,B negative B-cell line, CIR. The resulting transfectants were tested for binding to Chinese hamster ovary (CHO) cells expressing the human CD8 gene, using the assay described by Norment *et al.*<sup>3</sup>. Fifteen of 17 HLA-A,B molecules tested gave significant levels of positive binding, as did two murine class I MHC

TABLE 1 Binding of CD8 to class I molecules

Experiment	Transfected class I gene	Cells bound per well ( $\times 10^{-3}$ )	
		CD8 <sup>+</sup>	CD8 <sup>-</sup>
I	HLA-A2.1	32.2 $\pm$ 6.4	8.8 $\pm$ 0.8

	B51	41.7 $\pm$ 0.4	15.5 $\pm$ 1.2
III	untransfected CIR	26.1 $\pm$ 0.3	23.4 $\pm$ 0.5
	HLA-Bw58	39.6 $\pm$ 4.7	8.1 $\pm$ 2.1
	HLA-B7.1	20.2 $\pm$ 0.8	5.7 $\pm$ 1.2
	H-2D <sup>p</sup>	60.2 $\pm$ 9.7	11.7 $\pm$ 2.8
	H-2K <sup>b</sup>	86.7 $\pm$ 6.0	8.8 $\pm$ 5.9
	untransfected CIR	17.9 $\pm$ 2.2	14.1 $\pm$ 1.5

All transfectants were assayed as described in Fig. 1 legend. Results of three experiments are shown. The binding of class I transfected and untransfected CIR cells to CD8 expressing (CD8<sup>+</sup>) and non-expressing (CD8<sup>-</sup>) CHO cells is shown. Only HLA-Aw68.1 and HLA-Aw68.2 reproducibly showed no specific binding to CD8. The significance of variation in the positive binding of the other class I molecules is not known; it may result from differences in the properties of the individual transfectants and/or the affinity of the class I–CD8 interaction.

molecules, H-2K<sup>b</sup> and H-2D<sup>p</sup> (Table 1). These results indicate conservation of the CD8 binding site in class I molecules of humans and mice. It was therefore surprising to find that two human class I molecules; HLA-Aw68.1 and -Aw68.2, showed no specific interaction with CD8 in the cell–cell binding assay (Table 1). This effect cannot be attributed to differing levels of HLA-A expression by the various transfectants (Fig. 1) and most probably results from differences in their primary structures. Fortunately, HLA-Aw68.1 and -Aw68.2 are closely related in amino-acid sequence to molecules such as HLA-A2.1 and HLA-Aw69 which do bind CD8. For example, HLA-Aw69 and HLA-Aw68.1 differ at only six positions in the  $\alpha_2$  domain and one position (245) in the  $\alpha_3$  domain<sup>4</sup>. We therefore reasoned that one or more of these substitutions is responsible for the difference in CD8 binding. Furthermore, a comparison of over 50 HLA-A,B,C sequences identified 245 as the only position at which there is a substitution that is specific to HLA-Aw68.1 and -Aw68.2 (ref. 4 and unpublished observations). In these two molecules, Val occurs at position 245 whereas other HLA-A,B,C molecules have Ala. These considerations suggested the involvement of residue 245 and the  $\alpha_3$  domain in the CD8 binding site.

To test this hypothesis we made a pair of mutants: the Ala 245 of HLA-A2.1 was converted to Val, giving the A2.1m245 mutant; and the Val 245 of HLA-Aw68.1 was converted to Ala, giving the Aw68.1m245 mutant. Analysis of transfectants expressing these mutant genes showed that the CD8 binding phenotype correlated with the residue at position 245 (Fig. 1). Thus mutant A2.1m245 showed no binding to CD8 whereas mutant Aw68.1m245 bound CD8 equivalent to wild-type HLA-A2.1. The specificity of this binding was also identical to that obtained with wild-type HLA-A2.1, in that it was dependent on CD8 and could be inhibited by monoclonal antibodies against CD8 and class I HLA molecules. Results of similar experiments with various other mutants argue against the involvement of the  $\alpha_1$  and  $\alpha_2$  domains in binding CD8. In these mutants the six

69m95, 97, 245	I	M	W	H	Y	L	V	—
69m107, 245	V	R	G	H	Y	L	V	—
68.1m95, 97	V	R	G	R	D	W	V	—
68.1m107	I	M	W	R	D	W	V	—
Aw68.1	I	M	G	R	D	W	V	—

HLA-Aw69 and Aw68.1 differ only at the seven positions shown. Amino-acid substitutions in the HLA mutants are given by the standard single-letter code. Assays were performed as described in Fig. 1 legend.

differences (positions 95, 97, 107, 114, 116, 156) between HLA-Aw69, which binds CD8, and HLA-Aw68.1, which does not, were assessed. Conversion of various combinations of these substitutions from one sequence to the other had no effect on the CD8 binding phenotype, which in every case correlated with residue 245 (Table 2).

Previous speculation has suggested an Arg-Phe-Asp-Ser (RFDS) sequence, shared by many class I and class II MHC sequences and related to the fibronectin cell binding tetrapeptide Arg-Gly-Asp-Ser (RGDS), as a possible site for CD8 or CD4 binding<sup>5</sup>. Furthermore, Auffray *et al.* have shown that RFDS-containing peptides derived from class II sequences inhibit T-cell responses<sup>6</sup>. Conversely, the RFDS sequence of HLA-A2.1 (residues 35–38 of the  $\alpha_1$  domain) is, from the crystallographic structure, inaccessible and therefore an unlikely site for CD8 binding<sup>7,8</sup>. This view is supported by our finding that a mutant of HLA-A2.1 in which Arg 35 is substituted by Val shows no loss of CD8 binding activity (data not shown).

The question arises as to whether the differences in the cell-binding assay have functional consequences for cytotoxic T cells. To address this, we compared recognition of position 245 mutants by both alloreactive and antigen-specific, MHC-

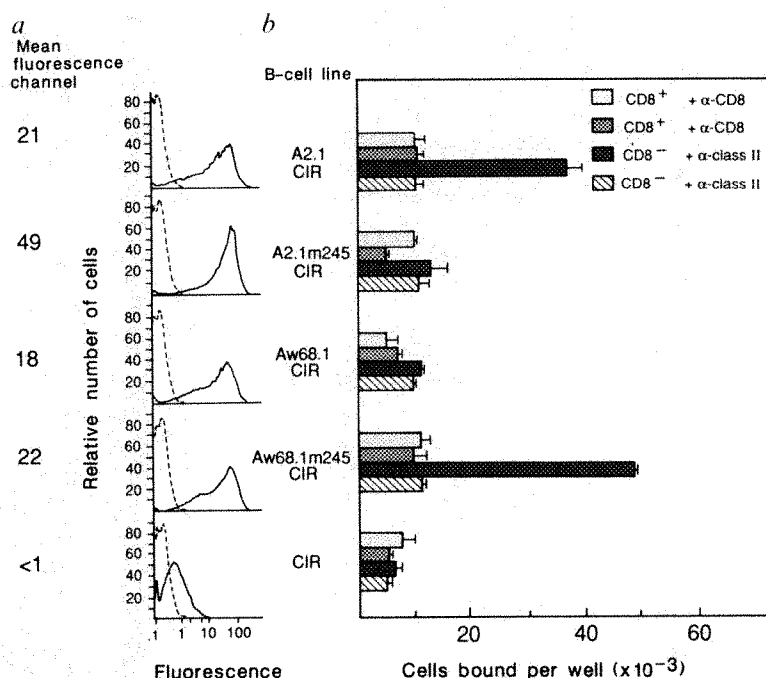

restricted CTL. The alloreactive CTL show specificity for HLA-A2.1 and effectively lyse the HLA-A2.1 transfectant. This lysis, however, is reduced by replacement of Ala 245 with Val (Fig. 2). By contrast, these CTL show a poor lysis of the HLA-Aw68.1 transfectant, which is considerably improved by replacement of Val 245 with Ala. Similar effects were observed with HLA-A2.1-restricted CTL lines specific for peptide 56–68 of the influenza matrix protein. Cytolysis was significantly reduced when Ala 245 of the HLA-A2.1 restriction molecule was replaced by Val (Fig. 2). Changes in CTL function can thus be correlated with changes observed in the cell-cell binding assay: greater lysis is observed when the target molecule binds more strongly to CD8.

Both alloreactive and antigen-specific CTL used in these experiments were inhibited by anti-CD8 monoclonal antibodies. Surprisingly, inhibition was not dependent upon whether the class I target could bind CD8 in the cell-cell binding assay. Thus recognition of HLA-Aw68.1 or HLA-A2.1m245 was inhibited by anti-CD8. In representative experiments, cytolysis by alloreactive CTL of HLA-Aw68.1 and HLA-A2.1 was, respectively, reduced from 29 to 8% and from 56 to 39% by anti-CD8 antibody 51.1. Lysis of peptide-sensitized A2.1m245 transfectants by influenza-specific CTL was reduced from 37 to 16% by anti-CD8, whereas no effect was seen on lysis of HLA-A2.1 transfectants. These observations might reflect a residual affinity of these molecules for CD8 that is not detected in the cell binding assay. An alternative is suggested by other studies in which the inhibition of CTL by anti-CD8 antibodies, in a manner that is unrelated to binding of class I molecules, is interpreted as evidence for a regulatory role for CD8 in T-cell activation<sup>9,10</sup>.

It is clear that substitution at position 245 alters the interaction of class I HLA molecules with CD8. This could result from a direct involvement of this residue in the interaction or by an indirect conformational effect on a distant site. The crystallographic structures of HLA-A2.1 and -Aw68.1 at high resolution have been determined and they are extremely similar (T. Garrett, M. Saper, P. Bjorkman and D. Wiley, unpublished observations). Thus, it is probable that the distinct functional properties

FIG. 1 Substitution at position 245 determines natural polymorphisms in CD8 binding. *a*, Expression of HLA-A2.1, A2.1m245, Aw68.1m245 and Aw68.1 molecules by transfectants of the CIR B-cell line which expresses no endogenous HLA-A,B molecules<sup>18</sup>. Indirect binding of the HLA-A2,A28-specific monoclonal antibody CR11-351 (ref. 19) (solid lines) was compared to an anti-actin control<sup>20</sup> (dotted lines) by flow cytometry. *b*, Binding of class I transfectants to CD8 expressing and non-expressing CHO cells in the presence of either anti-CD8 or anti-HLA-DR. Binding to CHO.1 and CHO.4 cells is labelled CD8<sup>+</sup> and CD8<sup>−</sup>, respectively. In each group of four results the combination of cells and antibodies is, going from top to bottom: CD8<sup>+</sup> CHO cells with anti-CD8 ( $\alpha$ -CD8); CD8<sup>−</sup> CHO cells with anti-CD8; CD8<sup>+</sup> CHO cells with anti-HLA-DR ( $\alpha$ -class II); CD8<sup>−</sup> CHO cells with anti-HLA-DR. The standard errors are indicated by the 'error' bars. The HLA-A2,A28-specific monoclonal antibody CR11-351 also inhibited cell-cell binding when preincubated with the CIR transfectants (data not shown). A second independently derived set of transfectants had identical CD8 binding characteristics (data not shown).

**METHODS.** Mutagenesis and transfection of class I genes were as previously described<sup>18</sup>. Flow-cytometric analysis of cells incubated first with monoclonal antibody and then with fluoresceinated goat anti-mouse antibody used a Becton-Dickinson FACS with a 10 $\times$  neutral density filter. In CD8 binding experiments, CIR transfectants with class I genes were radio-labelled with <sup>35</sup>S methionine, washed twice, resuspended in PBS-containing, 10% fetal calf serum, and incubated in 96-well plates with confluent monolayers of transfected CHO cells. The CHO cells were previously incubated (30 min, 20  $\mu$ g ml<sup>−1</sup>, 37 $^{\circ}$ ) either with monoclonal antibody 51.1 (ref. 21), which is specific for CD8, or CA206, which is specific for HLA-DR (ref. 22), and was used as an irrelevant antibody control. CHO.1

cells express no CD8 whereas CHO.4 cells express ~160-fold more CD8 than peripheral T cells<sup>3</sup>. After incubation at 37 $^{\circ}$  for 1 hour, wells were washed extensively, and bound radioactivity measured.

of these two molecules arise from the nature and disposition of the side-chains at the positions of amino-acid substitution and not through gross conformational differences. These observations combined with the complete change in CD8 binding phenotype caused by single substitutions at position 245 in HLA-A2.1 and HLA-Aw68.1 strongly favour the direct involvement of this residue and the  $\alpha_3$  domain in the CD8 binding site.

**FIG. 2** Cytolysis of class I HLA-expressing CIR transfectants by alloreactive and antigen-specific T cells. **a**, Lysis of CIR transfectants expressing HLA-A2.1, A2.1m245, Aw-68.1m245 and Aw68.1 by an HLA-A2 alloreactive CTL culture AJY. In some experiments, the A2.1m245 transfectants were lysed better than Aw68.1m245-bearing cells. In all experiments, however, the AJY culture recognized HLA-A2.1 more effectively than A2.1m245, and Aw68.1m245 more effectively than HLA-Aw68.1. **b**, Lysis by influenza-specific CTL of HLA-A2.1- and A2.1m245-expressing transfectants after incubation with peptide corresponding to residues 56–68 of the influenza matrix protein. Donor RM (HLA-A1,A2; Bw55, B44), left panel; donor DL (HLA-A2, A11; B27, B44), right panel. All but one of the responders lysed HLA-Aw68.1- or Aw68.1m245-bearing transfectants.  $\Delta$ ,  $\triangle$ : lysis of A2.1 transfectant with and without the Flu.m1 peptide, respectively.  $\bullet$ ,  $\circ$ : lysis of A2.1m245 transfectant with and without the Flu.m1 peptide, respectively.  $\blacksquare$ ,  $\square$ : lysis of untransfected CIR cells with and without the Flu.m1 peptide, respectively. **METHODS.**  $^{51}\text{Cr}$ -release assays were performed as previously described<sup>23</sup>. The AJY culture was generated by *in vitro* stimulation of peripheral blood lymphocytes (PBL) from a single donor AK (HLA-A3; B7, B38) with the HLA-A2.1-expressing cell line JY (ref. 23), and it lyses HLA-A2.1-, Aw69-, and Aw68-bearing targets with varying efficiency. Influenza-specific cultures were generated essentially as previously described<sup>24</sup>. PBL from six HLA-A2 positive donors were stimulated with  $10 \mu\text{g ml}^{-1}$  of a peptide (Flu.m1) derived from residues 56–68 of the influenza matrix protein shown previously to generate HLA-A2-restricted CTL (ref. 25). Three days after the initial stimulation, supernatant containing growth factors from IL-2-stimulated PBL was added. Cultures were restimulated after 7 days to generate secondary cultures. For cytolysis assays, target cells were preincubated overnight with  $10 \mu\text{g ml}^{-1}$  of the Flu.m1 peptide, then used in  $^{51}\text{Cr}$ -release experiments.

Further support for this interpretation comes from experiments showing that a mutant of H-2D<sup>d</sup> derived *in vitro* with a single substitution at position 227 shows specific loss of interaction with cytotoxic T cells that are dependent on Lyt-2, the murine equivalent of CD8<sup>11,12</sup>. Positions 227 and 245 of the  $\alpha_3$  domain are located proximal to the membrane attachment site in a solvent accessible surface region and are separated by only 10.5 Å (refs 7, 8). Both could therefore contribute to the CD8 binding site.

Davis and Bjorkman have raised the possibility that CD8 interacts with the  $\alpha_1$  and  $\alpha_2$  domains of class I MHC molecules, in a manner analogous to the T-cell receptor<sup>13</sup>. A consequence of this model is that simultaneous interaction of CD8 and the T-cell receptor with the same class I MHC molecule cannot occur. Our results and those of Potter *et al.*<sup>11,12</sup>, suggesting interaction of CD8 with the  $\alpha_3$  domain, do not support this view and leave open the possibility that a complex of T-cell receptor and CD8, binding to the same class I MHC molecule (plus its antigenic peptide), is crucial to T-cell activation.

Comparison of the amino-acid sequences of antigen-presenting class I MHC molecules from seven mammalian species (summarized in ref. 14) shows that HLA-Aw68.1 and -Aw68.2 are unique in not having Ala at position 245. This combined with the observation that all 15 molecules with Ala at this position bound CD8 in the cell-cell binding assay suggest that the non-binding CD8 phenotype will be rare among class I MHC products. In most human populations, however, the frequency of HLA-A28, of which HLA-Aw68.1 and -Aw68.2 are subtypes, is 8–9% (ref. 15). The intriguing question is whether reduced CD8 binding confers any selective advantage or disadvantage to individuals expressing these molecules. For example, does it affect the capacity of HLA-Aw68.1 and -Aw68.2 to present antigens, or the repertoire of HLA-Aw68.1- and HLA-Aw68.2-restricted T-cell receptors selected in the thymus? In studies by Rickinson *et al.* CTL specific for Epstein-Barr virus (EBV), generated by *in vitro* priming and restricted to HLA-Aw68, were never obtained, although HLA-Aw69-restricted CTL lysed infected HLA-Aw68 targets<sup>16,17</sup>. This suggests that although HLA-Aw68 can present EBV peptides to specific CTL, it may be deficient in generating such a response. The number of epitopes and restriction patterns described for human class I MHC molecules, however, is still too small to assess the relative use of HLA-Aw68.1 and -Aw68.2.  $\square$

THE molecular analysis of many genetic diseases requires the isolation of probes for defined human chromosome regions. Existing techniques such as the screening of chromosome-specific libraries<sup>1</sup>, subtractive DNA cloning<sup>2</sup> and chromosome jumping<sup>3</sup> are either tedious or not generally applicable. Microdissection and microcloning has successfully been applied to various chromosome regions in *Drosophila* and mouse<sup>4-9</sup>, but conventional microtechniques are too coarse and inefficient for analysis of the human genome<sup>10-12</sup>. Because microdissection has previously been used on unbanded chromosomes only, cell lines in which the chromosome of interest could be identified without banding had to be used. At least one hundred chromosomes were needed for dissection and  $\lambda$  vectors used to achieve maximum cloning efficiency. Recombinant phage clones are, however, more difficult to characterize than plasmid clones. Here we describe the dissection of the Langer-Giedion syndrome region on chromosome 8 from GTG-banded metaphase chromosomes (G-banding with trypsin-Giemsa) and the universal enzymatic amplification of the dissected DNA. Eighty per cent of clones from this library (total yield 20,000) identify single-copy DNA sequences. Fifty per cent of clones detect deletions in two patients with Langer-Giedion syndrome. Although the other clones have not yet been mapped, this result demonstrates that thousands of region-specific probes can be isolated within ten days.

We have isolated probes for the Langer-Giedion syndrome chromosome region (8q24.1) (refs 13, 14). Deletion of a set of unknown genes within this region leads to sparse hair, lax skin, bulbous nose, cone-shaped epiphyses, multiple cartilaginous exostoses and mental retardation<sup>15</sup>. Using an electronically controlled micromanipulator, we dissected the distal third of band 8q23 and the proximal two-thirds of sub-band 8q24.1 from normal GTG-banded chromosomes (Fig. 1). The dissected

region is estimated to comprise approximately 10,000 kilobases (kb). As the distal extent of the Langer-Giedion syndrome chromosome region is uncertain, we included chromosome material distal to the deletions in our two patients (see below and Fig. 3). To facilitate the identification and dissection of the chromosomes, the dissection was not performed in an oil chamber, and we used straight needles and pipettes, rather than microforged ones.

The dissected chromosome fragments were transferred to a collection drop kept in a moist chamber. After the dissection of 37 chromosomes, the microdrop was overlaid with oil. Chromosomal DNA (estimated yield, 0.5 pg) was digested with the restriction enzyme *RsaI* and ligated to a *SmaI*-cut pUC plasmid (Fig. 2). The inserts were then amplified by the polymerase chain reaction using the universal M13/pUC sequencing and reverse sequencing primers. In contrast to the amplification of specific DNA sequences in genomic DNA<sup>16</sup>, the universally primed polymerase chain reaction allows the simultaneous amplification of many different unknown DNA sequences. After 26 cycles of denaturation, annealing and DNA synthesis, the amplified inserts were released by *EcoRI* digestion and cloned into pUC13. We obtained 20,000 clones, of which we characterized 50 in detail.

The insert size ranged from 52 base pairs (bp) to 350 bp (mean, 150 bp). This is smaller than the mean size of *RsaI* restriction fragments (495 bp)<sup>17</sup>, probably because of the preferential amplification of small inserts. The cloning of small fragments has the advantage of yielding a high percentage of repeat-free clones: 10 inserts (20%) contained repetitive DNA and 40 inserts (80%) identified single-copy fragments. All but two of the single-copy clones were different. These clones were used to probe Southern blots containing DNA from two Langer-Giedion patients with a visible chromosome deletion.

Patient S.H. (ref. 18) has a deletion of band q23 and sub-band q24.11 (ref. 13); patient T.T. (ref. 19) has a deletion of the distal half of band q23 and the proximal half of sub-band q24.1 (ref. 13). Twenty clones (50%) map outside the deletions in S.H. and T.T. These clones are probably derived from the dissected material distal to the deletion in T.T., but cannot be assigned at present. Eleven clones are deleted in both patients, and nine clones are deleted in patient T.T. only (Fig. 3). These clones are currently being extended by chromosome walking and physically linked by pulsed-field gel electrophoresis. None of the microclones maps to the region deleted in S.H. only, which is proximal to the dissected region. This demonstrates the precision of our technique.

In addition to the region on chromosome 8, we have successfully dissected and cloned DNA from 11p13 (Wilms tumour-aniridia) and 15q11-12 (Prader-Willi syndrome). In these experiments, only 20 chromosomes were dissected and all of the clones tested so far map to the dissected bands. If desired,

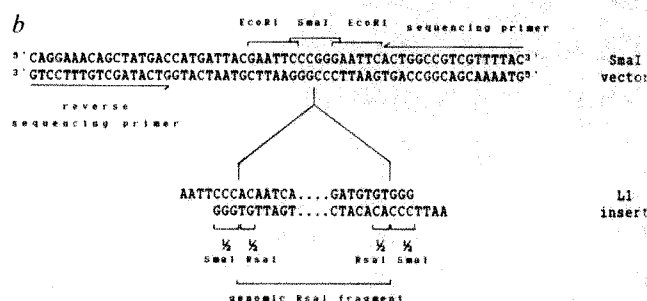

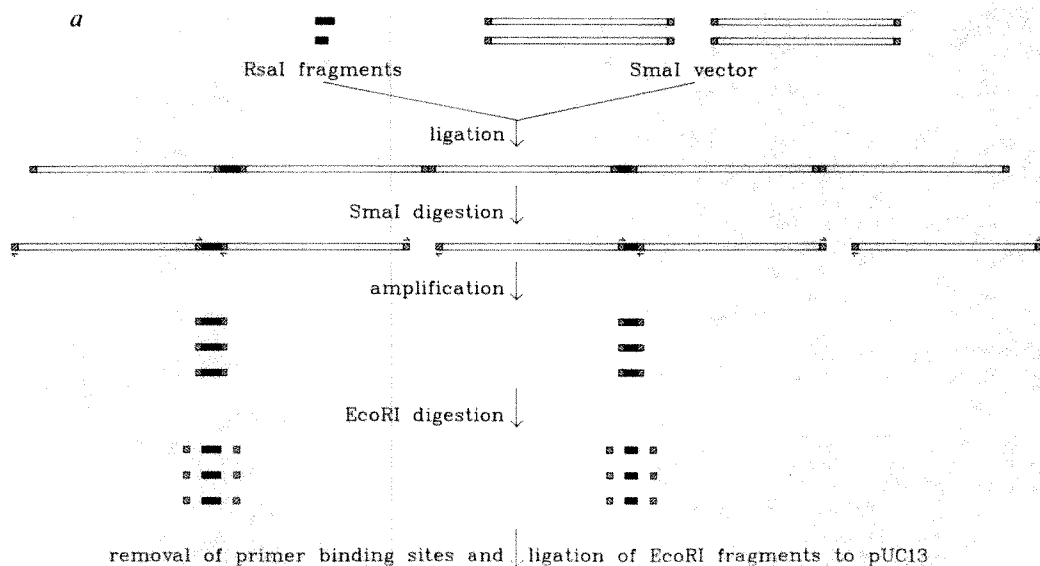

FIG. 1 Microdissection of chromosome 8. a, Human GTG-banded metaphase with two chromosomes 8, one dissected (8q23.3→8q24.21) and one not, for comparison. b, Diagram showing a normal G-banding pattern of a human chromosome 8 (ref. 20). The arrows on the left indicate the region dissected in all chromosomes 8. The arrows on the right mark the most proximal and most distal limits of the various cuts.

METHODS. Cells from normal amniotic fluid cell cultures were collected using the pipette method (time of fixation was 10–20 s)<sup>21</sup>. The chromosomes were spread onto clean coverslips, washed in 70% ethanol, air dried and GTG-banded. Microdissection was performed on an inverted microscope (IM Zeiss; magnification, 1,200 $\times$ ) with the aid of a micromanipulator (MR MOT; Zeiss) and extended siliconized glass needles. The dissected pieces ( $n=37$ ) were pooled into a 1-ml collection drop (10 mM Tris-HCl pH 7.5, 10 mM NaCl, 0.1% SDS, 1% glycerol, 500  $\mu\text{g ml}^{-1}$  proteinase K) which was situated in a small moist chamber on a separate siliconized coverslip. Proteinase K digestion and phenol extractions were performed under oil essentially as described<sup>9</sup>. The chromosomal DNA was digested with *RsaI* (Boehringer) at 37 °C for 2.5 h (final concentration 6 units  $\mu\text{l}^{-1}$ ). Another aliquot of *RsaI* was added, and the mixture incubated for another 2.5 h. The enzyme was inactivated by three phenol extractions.

**FIG. 2 Universal DNA amplification procedure.** *a*, *Rsa*I fragments (filled bars) are ligated to a fivefold molar excess of a *Sma*I-cut pUC vector (open bars) that contains a single *Sma*I site flanked by two *Eco*RI sites (see polylinker sequence in *b*). Polyethylene glycol is included in the ligation mixture to obtain long concatemers<sup>22</sup>. Nonrecombinant polylinker sequences are recut with *Sma*I, and inserts are amplified with the help of DNA polymerase and the universal M13/pUC sequencing (←) and reverse sequencing primer (→). After removal of the primer binding sites (hatched bars) by *Eco*RI digestion and gel filtration, the amplified fragments are cloned into pUC13. *b*, Polylinker sequence of the *Sma*I vector and insert sequence of clone L1. The *Sma*I vector is a pUC derivative with a single *Sma*I site flanked by *Eco*RI sites. It allows the ligation of *Rsa*I fragments into the *Sma*I site and the release of the amplified inserts by *Eco*RI digestion. The released fragments are cloned into the *Eco*RI site of pUC13 (Pharmacia). As shown for one example (clone L1), the clone inserts contain half a *Sma*I and half a *Rsa*I site at both ends.

**METHODS.** A synthetic *Eco*RI-*Sma*I adaptor (Pharmacia) was inserted between the two *Eco*RI sites of M13mp7 (BRL) to yield the symmetric polylinker sequence *Eco*RI-*Sma*I-*Eco*RI. The 320-bp *Pvu*II fragment spanning the polylinker sequence of this M13 derivative was then used to replace the respective *Pvu*II fragment of pUC19 to yield the *Sma*I vector. Chromosomal *Rsa*I fragments (estimated yield 0.5 pg) were ligated to 13.5 pg *Sma*I vector in the presence of 15% polyethylene glycol (relative molecular mass 8,000). T4 DNA ligase (New England Biolabs; 0.08 units) was added, and the ligation was carried out at 15 °C overnight. The reaction mixture (128 nl) was then taken up into 2 µl of water and transferred to a microfuge tube. After heat inactivation of the ligase, non-recombinant polylinker sequences were recut with 2 units of *Sma*I (Boehringer) at 25 °C for 1 hour (final volume 5 µl). The sample was adjusted to 50 µl of 20 mM Tris-HCl pH 7.8, 5 mM MgCl<sub>2</sub>, 1 mM dithiothreitol, 2.5 mM of each of the four deoxynucleoside triphosphates and 1 µM each of the M13/pUC sequencing and reverse sequencing primers. The DNA was denatured by incubation at 95 °C for 5 min, and the primers were allowed to anneal at 33 °C for 2 min. After the addition of 1 unit of Klenow DNA polymerase (MEDAC, Hamburg) in 1 µl amplification

buffer, DNA synthesis was carried out at 37 °C for 10 min. This cycle was repeated 25 times, except that subsequent denaturations were performed at 92 °C for 2 min, and the time for DNA synthesis was reduced to 5 min after the fifth cycle. After the last primer extension step, Klenow DNA polymerase was heat-inactivated and the amplification products were digested with *Eco*RI. The amplified fragments were purified by gel filtration through two successive Sephadryl S-200 spun columns (Pharmacia) and ligated to dephosphorylated *Eco*RI-cut pUC13 (Pharmacia). The ligation products were used to transform competent DH5α cells (BRL). Recombinant plasmids were purified on Qiagen-20 tips. DNA sequences were determined by the dideoxy chain-termination method<sup>23</sup>.

**FIG. 3 Chromosomal localization of the microclones.** *a*, Quantitative Southern blot analysis of Langer-Giedion syndrome patients. Genomic DNA from a normal control (C) and from the patients S.H. and T.T. was digested with *Hind*III and probed with the microclones indicated beside the bands. Hybridizations were performed essentially as described previously<sup>24</sup>. Various probes that map outside the deletions served as an internal hybridization standard (S). Each lane contains approximately the same amount of DNA. The relative intensity of the autoradiographic signals L32:S and L7:S was determined using a Shimadzu CS9000 densitometer and is given beneath each lane. Clone L32 is deleted in S.H. and T.T., and clone L7 is deleted in T.T. only. Similar results were obtained in two other independent experiments. The

the number and the size of the dissected fragments could be reduced much further, but the number of amplification cycles would have to be increased. The universal DNA amplification system also allows the cloning of minute amounts of DNA from ancient tissue samples and the construction of random primed cDNA libraries from small cell numbers.

larger L32 band in T.T. represents a rare allele of a *Hind*III restriction fragment length polymorphism<sup>25</sup>. *b*, All microclones were mapped by quantitative Southern blot hybridizations as shown above. In each case, three independent experiments were performed. The distal part of 8q and the deleted chromosome segments in S.H. and T.T. are shown. The numbers on the right refer to the clones found to be deleted in both patients and in T.T. only.

ACKNOWLEDGEMENTS. This work was supported in part by the Deutsche Forschungsgemeinschaft. We thank Dr S. Brown, Dr E. Fisher, Dr A. Greenfield and J. Cavanna for introducing us to microdissection, R. Burdick for technical assistance, Professor R. A. Pfeiffer and Dr B. Zabel for referring the patients to us, and Professor E. Passarge for continuous support.

## Isotype exclusion and transgene down-regulation in immunoglobulin- $\lambda$ transgenic mice

M. S. Neuberger\*, H. M. Caskey\*, S. Pettersson\*, G. T. Williams\* & M. A. Surani†

\*MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK

†Department of Molecular Embryology, Institute of Animal Physiology and Genetics Research, Babraham, Cambridge CB2 4AT, UK

A GIVEN B lymphocyte makes an antibody containing either  $\kappa$ - or  $\lambda$ -light chains, but not both<sup>1,2</sup>. This isotype exclusion is effected at the level of the rearrangement of the immunoglobulin gene segments<sup>3–5</sup>, although by an unknown mechanism. An attractive possibility is that, following productive rearrangement of one of the light-chain loci, the newly synthesized light-chain polypeptide inhibits DNA rearrangement for the other isotype. To test such feedback regulation, we have created transgenic mice carrying a rearranged  $\lambda_1$ -gene. By contrast with the B cells in normal newborn mice which are mainly  $\kappa^+ \lambda^-$ , the B cells in the newborn transgenic mice express  $\lambda$ - but not  $\kappa$ -chains. We propose that the synthesis of any light chain, be it  $\kappa$  or  $\lambda$ , that allows expression of IgM on the cell surface results in a cessation of all V–J joining. Interestingly, the limited light-chain repertoire of the transgenic mice does not persist and most adult B cells express endogenous  $\kappa$ -rearrangements and down-regulate the transgene.

Analysis of transgenic mice has provided strong evidence for a role for immunoglobulin polypeptides in mediating a feedback regulation of allelic exclusion<sup>6–10</sup>. Thus, a transgenic  $\kappa$ -gene inhibits rearrangement of the endogenous  $\kappa$ -loci<sup>7,8</sup>. It has not been established, however, whether the  $\kappa$ -transgene has a role in mediating isotype exclusion as, even in normal mice, rearrangement of the  $\lambda$ -loci is a rare event. We have therefore approached this problem by creating  $\lambda$ -transgenic mice to see whether the  $\lambda$ -transgene exerts an effect on rearrangement of the endogenous  $\kappa$ -loci. A plasmid was assembled that contains a rearranged mouse  $\lambda_1$ -gene linked to a chimaeric  $\alpha 2$ -heavy-chain gene (Fig. 1a). This  $\alpha 2$  gene lacks the exons encoding the membrane-anchoring sequences and the presence of this human  $\alpha 2$ -gene allowed unambiguous identification of mouse cells expressing the transgene. Transcription of both the heavy- and light-chain genes is potentiated by the mouse IgH enhancer.

Linearized plasmid DNA was injected into mouse eggs. Of 42 mice born, 12 carried integrations of the injected DNA. Nine

FIG. 1 Structure of plasmid DNA: thick filled lines; mouse immunoglobulin DNA; hatched lines, human immunoglobulin DNA; open boxes, IgH and SV40 enhancers; thin filled lines, pSV2gpt vector. Restriction sites are abbreviated: R, EcoRI; X, XbaI; H, HindIII; P, PvuII. The plasmid is a derivative of pSV-V<sub>H</sub>- $\alpha 2$  described previously<sup>21</sup> and contains a 7.4-kb EcoRI fragment including the rearranged  $\lambda_1$  gene of the mouse HOPC2020 plasmacytoma<sup>22</sup>. Plasmid DNA was linearized at the PvuII site in the vector and transgenic mice were derived as previously described<sup>23</sup>.

of these transgenic founder mice expressed the transgene as judged by enzyme-linked immunosorbent assays (ELISA) which detected the presence of IgA2, $\lambda_1$  anti-NP antibody in serum. Northern blot analysis (data not shown) revealed that expression of the transgene was lymphoid-specific. Most analyses were performed on descendants of founders 8,023 (which gave serum titres of  $\sim 5 \mu\text{g ml}^{-1}$  at 4 weeks of age) or 8,032 (serum titres of  $100\text{--}200 \mu\text{g ml}^{-1}$ ).

Analysis of cells from the offspring of founder 8,032 using the fluorescence-activated cell sorter (FACS) showed that the transgenic mice and their non-transgenic siblings contained similar proportions of IgM<sup>+</sup> B cells in their spleens (Fig. 2a). The newborn transgenic mice, however, differ radically from their littermates with respect to immunoglobulin light-chain expression. The transgenics have few  $\kappa$ -bearing B cells, most carrying  $\lambda$ -chains on the surface (Fig. 2a). Cytoplasmic immunofluorescence analysis gave similar results (Table 1) and revealed that most of the  $\lambda^+$ -cells stained for human  $\alpha 2$ , indicating that they were likely to be expressing the transgene rather than an endogenous  $\lambda$ -gene. By contrast with the non-transgenic siblings, however, the isotype exclusion in the transgenic mice, although impressive, is far from absolute, with  $\sim 10\%$  of the B cells making both  $\kappa$ - and  $\lambda$ -chains (Table 1). The  $\alpha 2$ -heavy-chain itself was detected only intracytoplasmically.

Transgene expression among splenic B cells of adult transgenic mice contrasts strikingly with that in the neonates. The proportion of  $\lambda$ -expressing cells decreases considerably with age and there is a corresponding increase in the number of B cells that express  $\kappa$ -light chains (Fig. 2a and Table 1). This fall with age in the proportion of transgene-expressing cells is observed in F<sub>1</sub> and subsequent generation offspring of both the 8,023 and 8,032 founders. We believe that a small proportion

TABLE 1 Cytoplasmic immunofluorescence analysis of immunoglobulin light-chain expression

	Transgenic		Control	
	Neonates	Adults	Neonates	Adults
$\lambda$ -only	73	25	17	3
$\kappa$ , $\lambda$ -doubles	10	9	0	0
$\kappa$ -only	17	66	83	97

Results in each column show the percentage of total light-chain-positive spleen cells from pools of 3 mice of 8,032 offspring which type as  $\kappa$ -only,  $\lambda$ -only or  $\kappa$ ,  $\lambda$ -doubles. Neonatal mice were 4 days old and adults 9 weeks old. Immunofluorescence on methanol-permeabilised cells was carried out using a fluorescein isothiocyanate (FITC)-conjugated goat anti-mouse  $\lambda$ -antisera (Southern Biotechnology) and biotinylated goat anti-mouse  $\kappa$ -antisera (Amersham) with phycoerythrin-conjugated streptavidin. It is notable that in the strain of mice used here (C57BL/6  $\times$  CBA F<sub>1</sub>), the proportion of  $\lambda^+$  cells in non-transgenic neonates is somewhat higher than that reported previously<sup>25</sup> for BALB/c and C57BL/6.

FIG. 2 Fluorescence analysis of transgene expression. FACS profiles of spleen cells surface-labelled with biotinylated sheep anti-mouse  $\kappa$ ,  $\lambda$  or  $\mu$  antibodies and fluorescein-conjugated streptavidin; dead cells were gated out by scatter gating. Samples were obtained from 3 day or 8-week-old offspring of 8.032. The results shown here are from four individual mice although similar profiles were obtained from other siblings using both neonatal and adult  $F_2$  offspring of both 8.023 and 8.032.

of B cells either fails to activate or, alternatively, down-regulates expression of the transgene; these cells then undergo rearrangement of the endogenous light-chain loci, and selection at the cellular level results in the temporal change in antibody expression<sup>11</sup>.

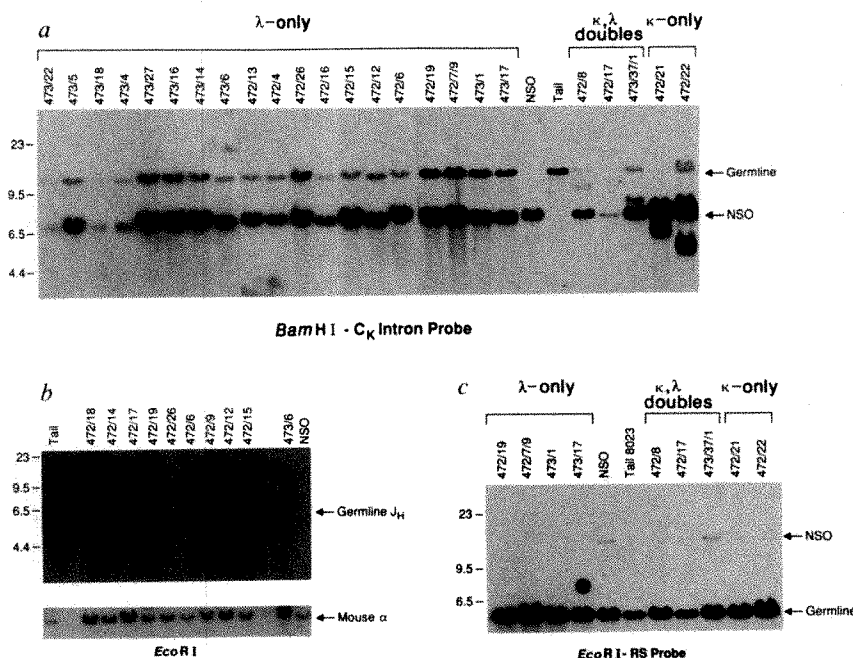

Hybridomas were established to ascertain whether the inhibition of  $\kappa$ -light-chain expression in the transgenic mice was due to an inhibition of  $\kappa$ -gene rearrangement. Spleen cells from 3.5- or 8-week-old transgenic mice were fused with the NS0 plasmacytoma. DNA was prepared from 22 randomly chosen cloned hybridomas that secreted  $\lambda$ -light chains. Of these 22 clones, three turned out to be  $\kappa$ , $\lambda$ -double producers with the other 19 making  $\lambda$  as their sole light chain. Southern blot analysis (Fig. 3a) revealed that the  $\kappa$ -loci of spleen cell origin in the  $\lambda$ -only hybrids were always in the germline configuration, in stark contrast to those from  $\lambda$ -expressing B cells of non-transgenic

mice which normally bear aberrant  $\kappa$ -rearrangements on one or both alleles<sup>3-5,12</sup>. Furthermore, the state of the  $\kappa$ -loci in the  $\lambda$ -hybridomas from the transgenic mice also contrasts with the  $\kappa$ -loci in random hybridomas made by fusing spleen cells from normal (CBA  $\times$  C57BL/6) $F_1$  mice with NS0. In this case, DNA was analysed from randomly chosen, cloned hybridomas whether or not they produced immunoglobulin. Consistent with previous observations on primary cells<sup>13</sup>, we found that the incoming  $\kappa$ -gene was rearranged in 9 out of 20 of these hybrids (data not shown). These results show therefore that the presence of the IgA2, $\lambda_1$  transgene leads to an inhibition of  $\kappa$ -gene rearrangement.

The mechanism regulating the hierarchy of rearrangements at the light-chain loci remains a mystery. Apart from aberrant  $V_{\kappa}$ - $J_{\kappa}$  joining, most  $\lambda$ -expressing hybridomas contain rearrangements involving the rearranging sequence element (RS)<sup>14,15</sup>. This element, which in man is termed  $\kappa$ -deleting element (kde)<sup>16,17</sup>, is located ~24 kilobase (kb) downstream of the  $C_{\kappa}$  exon and recombines with the joining signals belonging to a  $V_{\kappa}$  segment or in the vicinity of the  $J_{\kappa}$  elements with resultant destruction of the  $\kappa$ -locus. The significance of this RS recombination is not known. It has been proposed that it acts as a signal to initiate rearrangement at the  $\lambda$ -loci<sup>14</sup>. It is also possible, however, to envisage models in which productive  $\lambda$ -rearrangement triggers RS recombination and thereby ensures isotype exclusion. To test this second model, we looked at the status of the RS element in the  $\lambda$ -expressing hybridomas from the transgenic mice. Two main bands hybridizing with the RS probe are clearly visible (Fig. 3c); the strong 6-kb *Eco*RI fragment containing the germline RS element and a weak 13-kb band containing the rearranged RS of NS0. Several of the hybrids have lost the rearranged RS of the fusion partner, presumably through chromosome loss although we have no simple explanation for the fact that loss of the NS0, rearranged RS allele is particularly evident in the hybrids that express only  $\lambda$ -light chains. There is no evidence, however, of additional RS rearrangements in most of the hybridomas although one (NW473/22, a  $\lambda$ -only expresser, not shown) contains extra bands that hybridize weakly with the RS probe. On the basis of these results, it seems improbable that RS recombination is specifically activated by the presence of  $\lambda$ -light chains. Therefore, if RS recombination does indeed have a role in isotype exclusion it is more likely to lie in the activation of  $\lambda$ -rearrangement rather than in enabling  $\lambda$ -chains to switch off  $\kappa$ -rearrangement.

FIG. 3 Southern blot analysis of  $\kappa$ , IgH and RS rearrangements in splenic hybridomas. a,  $\kappa$ -rearrangements: DNA digested with *Bam*HI was probed with an *Xba*I-*Hind*III fragment from the mouse  $J_{\kappa}$ - $C_{\kappa}$  intron. The bands labelled NS0 are from the NS0 fusion partner and Germline indicates the band corresponding to the germline, unrearranged  $\kappa$  locus. b, IgH rearrangements: DNA was digested with *Eco*RI and probed with a 0.6-kb *Sac*I-*Bsu*36I fragment from between D-Q52 and  $J_{\mu}$ 1. The blot was then reprobed for the mouse immunoglobulin  $\alpha$ -heavy-chain gene so as to provide a control for DNA loading. c, RS rearrangements: DNA was digested with *Eco*RI and probed with an 0.8-kb *Sau*3A fragment (probe rs0.8 of ref. 15) for RS sequences. N indicates the rearranged RS element of the NS0 fusion partner and G indicates the germline-configuration RS band.

**METHODS.** The hybrids were derived by fusing spleen cells from an 8-week-old offspring of 8.023 (NW472 hybrids) or a 3.5-week-old offspring of 8.032 (NW473 hybrids) with NS0 plasmacytoma cells. After growth in selective medium, hybrids were cloned by limiting dilution.

Apart from the inhibition of  $\kappa$  rearrangement, the transgenic mice also exhibit a decreased amount of rearrangement at the IgH loci. Of a total of 25 random  $\lambda^+$ -hybrids examined from the transgenic mice, 13 (52%) contained a germline  $J_H$  allele as detected using a probe for the region located between D-Q52 and  $J_H1$  (one of the blots is shown in Fig. 3b). This is a considerably higher figure than would be expected from an analysis of IgH rearrangements both in primary B cells<sup>18</sup> as well as in random hybrids generated by fusing spleen cells from (C57BL/6  $\times$  SJL) mice with X63.Ag8.653 (ref. 10). We cannot formally exclude the possibility that this inhibition is due to the secreted form of the human  $\alpha 2$  heavy-chain polypeptide. A similar inhibition of IgH rearrangement, however, has recently been described in mice transgenic for a  $\kappa$ -light-chain gene where 22% of the hybrids were found to contain a germline  $J_H$  allele<sup>19</sup>. By analogy with the proposal of Manz *et al.*<sup>19</sup>, we suspect that the increased frequency of germline  $J_H$  loci in the hybridomas from the IgA2, $\lambda 1$  transgenic mice is probably caused by a combination of transgenic  $\lambda 1$  chain with the endogenous  $\mu_m$ -polypeptide leading to an early switch off of recombinase activity in pre-B-cells that have just rearranged their endogenous IgH locus. This could then lead to a diminished amount of D- $J_H$  rearrangement on the excluded IgH allele. The fact that we see a higher proportion of germline  $J_H$  alleles in the IgA2, $\lambda 1$  transgenic mice than has been described in the  $\kappa$ -transgenics could be due to that fact that expression of the  $\lambda 1$  transgene is potentiated by the IgH enhancer; it may therefore be switched on earlier than the  $\kappa$  transgene. Because of this inhibition of both heavy and light chain rearrangement, it is not surprising that the transgene causes an overall depression of B-cell development as the number of spleen cells in the transgenic mice was  $\sim 70\%$  that of their non-transgenic siblings.

The analysis of immunoglobulin light-chain gene expression in mouse plasmacytomas and in hybridomas from mice transgenic for a  $\kappa$ -light chain<sup>7,8,12</sup> supports a model in which  $V_\kappa$ - $J_\kappa$  joining is switched off following a signal delivered by a complete IgM, $\kappa$  antibody molecule. Recent data obtained using both transgenic mice and pre-B-cell lines were consistent with the membrane form of the IgM antibody mediating this feedback regulation<sup>9,20</sup>. From the work described here it is clear that a transgenic  $\lambda$ -light chain (presumably in association with the endogenous  $\mu_m$ -polypeptide) causes an inhibition of  $\kappa$ -locus rearrangement. It is probable that, following the production of intracellular  $\mu_m$  polypeptide chains, any light-chain rearrangement be it  $\lambda$  or  $\kappa$  that leads to IgM on the cell surface results in a cessation of all V-J joining. It is attractive to speculate that whereas the presence of  $\mu_m$ -polypeptide in the membrane of the endoplasmic reticulum signals a stop to heavy-chain rearrangement and a start to light-chain rearrangement, productive light-chain rearrangement causes the  $\mu_m$ -polypeptide to be translocated to the plasma membrane where it signals to stop all V-gene rearrangement. □

## A dominant control region from the human $\beta$ -globin locus conferring integration site-independent gene expression

Dale Talbot, Philip Collis, Michael Antoniou, Miguel Vidal, Frank Grosveld & David R. Greaves

Laboratory of Gene Structure and Expression, National Institute for Medical Research, The Ridgeway, Mill Hill, London NW7 1AA, UK

THE regulatory elements that determine the expression pattern of a number of eukaryotic genes expressed specifically in certain tissues have been defined and studied in detail. In general, however, the expression conferred by these elements on genes reintroduced into the genomes of cell lines and transgenic animals has turned out to be at a low level relative to that of endogenous genes, and influenced by the chromosomal site of insertion of the exogenous construct. We have previously shown that if regions flanking the human  $\beta$ -globin locus are introduced into the mouse genome along with the human  $\beta$ -globin gene, a level of expression comparable to that of endogenous genes can be achieved that is also independent of integration site<sup>1,2</sup>. We have now defined a dominant control region with these properties consisting of 6.5 kilobases of DNA encompassing erythroid cell-specific DNase I hypersensitive sites. The identification of such dominant control regions could have important applications in somatic gene therapy.

The human  $\beta$ -globin 'minilocus' construct contained 21 kilobases (kb) of DNA from the region 5 to the  $\epsilon$ -globin gene encompassing four erythroid cell-specific DNase I hypersensitive sites and 12 kb of DNA 3' to the human  $\beta$ -globin locus<sup>1</sup>. To investigate the properties of these dominant control region (DCR) sequences, the 33 kb 5' and 3' sequences were replaced by a 6.5 kb DNA fragment containing only the upstream hypersensitive sites<sup>1,3,4</sup> (Fig. 1). Construct 1359 contains the four hypersensitive sites in the same orientation relative to the  $\beta$ -globin gene (and the *tk-neo*<sup>r</sup> gene; tk, thymidine kinase; neo<sup>r</sup>, neomycin-resistance) as that found on chromosome 11. Construct 1400 has the DNase I hypersensitive sites in the opposite orientation and 1401 and 1357 have the four DNase I hypersensitive sites placed 3' to the  $\beta$ -globin gene (Fig. 1).

The insert of construct 1359 was injected into fertilized mouse eggs and 56 embryos were collected after 13.5 days of gestation. Thirteen transgenics were obtained in two groups as defined by S1 nuclease protection (Fig. 2a) and Southern blot analysis to measure the expression levels and copy number of the human  $\beta$ -globin gene in the fetal liver (Table 1). Members of the first group expressed the insert at low levels because they were mosaics (three mice, for example lane 2), or carried a deletion in the insert (two mice, for example lane 3). The remainder express the gene at high levels in a copy-number dependent way: five of these looked normal (for example lane 4) and three looked anaemic (for example lane 1). These results are therefore similar to those obtained with the minilocus<sup>1</sup> and show that full erythroid-specific activation is obtained by the small reconstructed DCR, sometimes leading to a thalassaemia-like anaemia.

To study the different  $\beta$ -globin constructs and avoid mosaicism, three independent, stably transformed, MEL cell popula-

tions were generated for each construct<sup>1</sup>. RNA was prepared before (-) or after (+) differentiation<sup>5</sup> and analysed on northern blots with probes of similar specific activity. Figure 2b shows that human  $\beta$ -globin mRNA is present at levels as high as those of endogenous mouse globin mRNA after induction. For comparison, Fig. 2b shows equal amounts of RNA from two populations using a construct (1273) without the DCR. Human  $\beta$ -globin expression is increased at least 100-fold by the addition of the four DNaseI hypersensitive sites and this high level of expression is observed in all orientations and relative positions (1359, 1400, 1401 and 1357). Moreover, this level of expression seems to be higher than that seen previously with the  $\beta$ -globin minilocus<sup>2</sup> (1016, Fig. 2b). We used S1 nuclease analysis to quantitate the levels of mRNA using probes for the human  $\beta$ , mouse  $\alpha$  and mouse  $\beta^{\text{maj}}$  globin genes (Fig. 3a and Table 1). Hybridization signals from Southern blots to probes for *tk-neo*<sup>r</sup> and human  $\beta$ -globin genes were compared to those from the endogenous single-copy mouse *Thy-1* gene and average  $\beta$ -globin gene copy numbers were calculated (Fig. 3b, Table 1). The expression per gene copy ratio is 120% per human  $\beta$ -globin gene compared to the endogenous mouse  $\beta^{\text{maj}}$ -globin gene (see Table 1 legend). As observed in the embryos, the expression levels seem to be directly proportional to the gene copy number

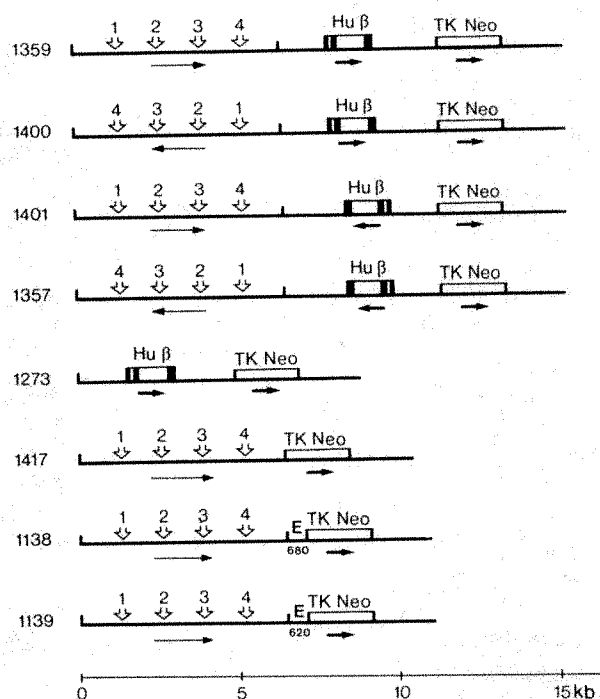

FIG. 1 Construction of the human  $\beta$ -globin plasmid locus.

**METHODS.** Plasmids 1359, 1400, 1401 and 1357 were constructed using restriction endonuclease fragments encompassing the 5' DNaseI hypersensitive sites ligated into a pPoly-III-I vector (a gift from A. J. Clark, Edinburgh) in the same orientation as in the normal  $\beta$ -globin locus: 2.1 kb *Bam*HI-*Xba*I fragment containing hypersensitive site 1, a 1.9 kb *Hind*III fragment containing hypersensitive site 2, a 1.5 kb *Asp*718-*Bgl*II fragment containing hypersensitive site 3 and a 1.0 kb partial *Sst*I-*Hind*III fragment containing hypersensitive site 4. A 6.5 kb *Not*I fragment containing all of the restriction fragments of the hypersensitive sites was then cloned into a Bluescript vector (1273) containing the 4.8 kb *Bgl*II fragment of the human  $\beta$ -globin gene<sup>1</sup> and a 2.7 kb partial *Eco*RI *tk-neo*<sup>r</sup> gene fragment from the cosmid pTCF (ref. 15). Vertical arrows show arrangement of the hypersensitive sites in the dominant control regions but do not show their actual positions within these constructs. Construct 1417 contains the 6.5 kb *Not*I fragment containing the four 5' hypersensitive sites cloned into a specially designed polylinker in a pUC18 vector containing the 2.0 kb partial *Nar*I-*tk-neo*<sup>r</sup> gene fragment. Construct 1138 contains the 680 bp *Dra*I-*Acl*I fragment of the 3' human  $\beta$ -globin enhancer cloned between the *Kpn*I and *Cla*I sites of 1417. Construct 1139 contains the 620 bp *Dra*I fragment of the internal enhancer of the human  $\beta$ -globin gene<sup>9</sup>. Construct 1016 is the  $\beta$ -globin minilocus cosmid<sup>1,2</sup>.

as was observed for the human  $\beta$ -globin minilocus<sup>1,2</sup>, although this argument is weakened by the fact that all the MEL populations generated have a similar average gene copy number (Fig. 3b, Table 1).

Figure 2b also shows that the 6.5 kb DNA fragment activates the heterologous herpes simplex virus (HSV) *tk* promoter in a similar way (compare 1359 to 1273). Unlike  $\beta$ -globin expression however, *neo*<sup>r</sup> transcripts are present at about the same level as with the  $\beta$ -minilocus cosmid (ref. 2 and 1016), possibly because the *tk-neo*<sup>r</sup> in the minilocus may already be transcribed maximally. Another difference between the minilocus and plasmid constructs is the higher level of  $\beta$ -globin and the *tk-neo*<sup>r</sup> transcripts before erythroid induction (Fig. 2b and ref. 2). This may be due to the loss of specific sequences or to the greatly reduced size of the constructs. Therefore, the reconstructed DCR does not isolate the  $\beta$ -globin gene from the effects of flanking sequences before differentiation.

To investigate further the activation of the heterologous HSV *tk* promoter, constructs were prepared which carried the 6.5 kb DCR without any human  $\beta$ -globin gene sequence (1417) or carrying the previously described enhancers, either from within (1139) or from the 3' flanking region of (1138) the  $\beta$ -globin gene<sup>6,7,8,9</sup>. Activation and erythroid inducibility of the HSV *tk* promoter is not dependent on the promoter or enhancers of the  $\beta$ -globin gene (Fig. 2c).

Interestingly the human  $\beta$ -globin gene expression per gene copy is increased, when compared to the  $\beta$ -globin minilocus (1016, Fig. 2b), but the *tk-neo*<sup>r</sup> expression remains the same. The transcription machinery of the *tk* promoter may have been

Copy numbers of human  $\beta$ -globin (Hu  $\beta$ ) were determined by Southern blotting and laser densitometry as described. Background-corrected Cerenkov counts for human  $\beta$ -globin, mouse  $\beta$ -globin major and mouse  $\alpha$ -globin protected fragments were expressed as ratios of the exogenous human  $\beta$ -globin message (Hu  $\beta$ ) to the endogenous mouse  $\alpha$  and  $\beta^{\text{maj}}$  signals (Ma and Mb<sup>maj</sup>), correcting for relative specific activities. This expression ratio was then reduced to an expression per gene copy ratio by dividing it by the ratio of the number of copies of human  $\beta$ -globin to the number of endogenous gene copies (two for mouse  $\beta$ -globin major and four for mouse  $\alpha$ -globin). Clones a and h seem to have threefold lower human  $\beta$ -globin expression than the average minilocus MEL population due to the loss of endogenous mouse  $\beta$ -globin genes<sup>2</sup>. ND, not determined, \* Anaemic.

saturated, which also explains why the addition of human  $\beta$ -globin gene enhancers to the 6.5 kb DNA fragment does not result in any further increase in the number of *tk-neo*<sup>r</sup> transcripts in MEL cell populations (Fig. 2c). We therefore suggest that a requirement for reproducible but low expression levels of biologically active molecules could be met by the combination of the DCR and inefficient or mutagenized promoters.

DNaseI fadeout analysis of nuclei from uninduced cells

FIG. 2 Analysis of human  $\beta$ -globin expression. *a*, S1 nuclease protection analysis of RNA from the transgenics (sizes are shown on the right). *b*, Northern blot of RNA prepared before (–) or after (+) differentiation of the stably transformed MEL cell lines. Lanes marked 1016 contain RNA from a MEL cell clone stably transfected with the human  $\beta$ -globin minilocus<sup>2</sup>. Wt, RNA from untransfected MEL C88 cells. The probes were for human  $\beta$ -globin (760 bp *EcoRI*–*MspI*) or the *tk-neo*<sup>r</sup> gene (580 bp *SphI*–*BglII*). The filter initially probed with human  $\beta$ -globin was reprobed with both the mouse histone H4 probe (460 bp *EcoRI*–*Tth111I*) and the mouse  $\alpha$ -globin probe (300 bp *BamHI*). *c*, Northern blot of total RNA (10  $\mu$ g) from uninduced (–) and induced (+) transfected C88 cell populations, probed simultaneously with the *tk-neo*<sup>r</sup> probe, the mouse  $\alpha$ -globin probe and the mouse histone H4 probe.

**METHODS.** In (*a*), an 11.5 kb *EcoRV* fragment from construct 1359 was gel-purified and microinjected into fertilized mouse eggs<sup>1</sup>. The levels of human  $\beta$ -globin mRNA were determined by S1 nuclease analysis with a mixture of probes for the human  $\beta$ -globin and mouse  $\beta$ <sup>maj</sup>-globin genes<sup>1,2</sup>. After autoradiography, each band was excised from the gel, placed at the bottom of an Eppendorf tube and quantitated by Cerenkov counting. A local background count was obtained by measuring a gel slice immediately above the band of interest and was subtracted from the actual count in subsequent calculations (see Table 1). For the Northern blots (*b*, *c*), plasmid DNA of indicated constructs (100  $\mu$ g) was linearized by digestion with *PvuI* and introduced into MEL C88 cells by electroporation<sup>9</sup>. Three independent G418-

shows that the hypersensitive sites 1–4 are regenerated in uninduced MEL cells, but not in L-cells with the exception of site 3 (data not shown and ref. 2). Weaker DNaseI hypersensitive sites can be seen on the  $\beta$ -globin gene promoter, 3' enhancer and *tk-neo*<sup>r</sup> promoter. Therefore, at this level of resolution, the establishment of an 'active' chromatin configuration is separable from full  $\beta$ -globin gene transcription.

The human  $\beta$ -globin gene constructs in these experiments are

resistant populations of 50–100 clones were generated for each construct. Total RNA (10  $\mu$ g) isolated by LiCl/urea extraction<sup>16</sup> from uninduced MEL cells, and MEL cells induced to differentiate by the addition of 2% v/v dimethyl sulphoxide (+) for five days, was electrophoresed on duplicate 1.5% agarose denaturing gels containing 0.7% formaldehyde and ethidium bromide (1  $\mu$ g ml<sup>–1</sup>) blotted to nitrocellulose and probed.

FIG. 3 S1 nuclease analysis and copy number determinations. *a*, S1 nuclease analysis of total RNA from uninduced (–) and induced (+) MEL cells. *b*, Southern blotting of genomic DNA from MEL populations.

**METHODS.** (*a*) Total RNA (10  $\mu$ g) from uninduced (–) and induced (+) populations of MEL cells were hybridized to a mixture of mouse  $\beta$ -globin major, mouse  $\alpha$ -globin and human  $\beta$ -globin probes described previously<sup>1,2</sup>. Relative specific activities were 1, 10 and 8, respectively, for the above probes. Three controls containing 30  $\mu$ g of RNA (3  $\times$  RNA) were performed to prove that the S1 probes were in excess. Quantitation was as described in Fig. 2a. 1016 RNAs are from two MEL cell clones containing the human  $\beta$ -globin minilocus<sup>2</sup>. Sizes are shown on the right. *b*, Genomic DNA (8  $\mu$ g) of MEL populations was digested with *EcoRI* and electrophoresed on a 0.6% agarose gel. After Southern blotting, the filter was probed with human  $\beta$ -globin intervening sequence probe (900 bp *BamHI*–*EcoRI*) and subsequently with a *tk-neo*<sup>r</sup> resistance probe (580 bp *SphI*–*BglII*), a mouse Thy-1 probe (M Thy 1) (600 bp *PstI*) and a histone H4 probe (MH4) (460 bp *EcoRI*–*Tth111I*). Laser densitometry using a range of autoradiographic exposures was used to quantitate human  $\beta$ -globin copy number. Mouse Thy-1 and histone H4 were used to correct for DNA loading. Human placental DNA was used to obtain an estimate of the actual  $\beta$ -globin copy

number. The human  $\beta$ -globin copy number of the populations of cells containing 1359 were compared to the other constructs through the *tk-neo*<sup>r</sup> gene signal as the *EcoRI* digestion gave a larger 9.3 kb human  $\beta$ -globin *EcoRI* fragment.

integrated at different sites into host cell DNA and have been replicated as chromatin. This contrasts with transient transfections using extra-chromosomal DNA templates not packaged into chromatin. Viral enhancers can stimulate  $\beta$ -globin gene expression several hundredfold in transient assays<sup>10</sup>, but this is not observed after stable integration, and levels of expression are dependent upon the site of integration into host DNA.

The observation that only 6.5 kb of DNA from the 5' boundary of the human  $\beta$ -globin locus allows high levels of expression of the human  $\beta$ -globin gene and the heterologous *tk-neo*<sup>r</sup> gene in erythroid cells has implications for the prospects of somatic gene therapy. Currently, the most realistic approach for therapy of a  $\beta$ -globin gene disorder (thalassaemia or sickle-cell anaemia) is by *in vitro* retroviral infection of bone marrow and transplantation<sup>11-14</sup>. Retroviruses carrying the human  $\beta$ -globin gene give rise to low levels of expression that are dependent upon the site of integration. The observation that the DCR works equally efficiently in all orientations and positions should facilitate production of retrovirus stocks with higher titres. The size of the reconstituted DCR with a smaller human  $\beta$ -globin gene

is within the range that can be packaged into retroviral particles. Such constructs have been made and are currently being tested. □

<sup>§</sup> Present address: Department of Zoology, University of California at Davis, Davis, California 95616, USA

KINESIN is a mechanoenzyme which uses energy liberated from ATP hydrolysis to transport particles towards the 'plus ends' of microtubules<sup>1-6</sup>. The enzyme consists of two polypeptide heavy chains of relative molecular mass ( $M_r$ )  $\approx$  110,000-140,000 (110K-140K) plus copurifying light chains; these polypeptides are arranged in a structure consisting of two globular heads attached to a fibrous stalk which terminates in a 'feathered' tail<sup>7-11</sup>. Here we report that a function-disrupting monoclonal antikinesin, which binds to the 45K fragment of the kinesin heavy chain<sup>12,13</sup>, recognizes an epitope located towards the N-terminal end of the heavy chain, and decorates the two globular heads lying at one end of the intact molecules (one antibody per head). The results show

that the two heavy chains of native kinesin are arranged in parallel, and that the 45K fragments, which display nucleotide-sensitive interactions with microtubules<sup>12,13</sup>, represent mechanochemical 'heads' located at the N-terminal regions of the heavy chains. Thus, it is likely that the kinesin heads are analogous to the subfragment-1 domains of myosin.

Electron microscopy<sup>7,10,11</sup> and DNA sequence analysis<sup>15</sup> indicate that kinesin heavy chains are organized into distinct domains. We have obtained evidence for such domains from the proteolytic cleavage of kinesin, which yields heavy-chain fragments of  $M_r \approx$  45K and 76K<sup>12,13</sup>. The 45K fragment is bound by three monoclonal antikinesins that inhibit kinesin-driven microtubule motility<sup>12</sup>, one of which, SUK 4, was used in the present study. Interestingly, the proteolysis reaction that produces the SUK 4-reactive 45K fragments is nucleotide- and microtubule-sensitive (Fig. 1). Irrespective of the presence or absence of microtubules, the 130K kinesin heavy chain is resistant to cleavage in the absence of nucleotide whereas the formation of the 45K peptide is enhanced by magnesium ATP. In the absence of microtubules, MgATP also promotes the formation of a small quantity of a 25K subfragment of the 45K fragment (Fig. 1, lane 5). The presence of AMPPNP (an unhydrolysable ATP analogue) or ADP seems to favour subdigestion of the 45K domain in the absence of microtubules; consequently no SUK 4-reactive products are visible on immunoblots. The 45K fragment is, however, stabilized by the presence of microtubules in AMPPNP or ADP. It seems therefore that the proteolytic reactions that produce and subdigest the 45K fragment are affected by the conformational differences of kinesin-micro-

FIG. 1 Nucleotide and microtubule-sensitive proteolysis of sea-urchin kinesin 130K heavy chains. *a*, Coomassie-stained SDS polyacrylamide gel; *b*, corresponding immunoblot probed with the function-blocking monoclonal antikinesin SUK 4, which binds to the 45K peptide<sup>12</sup>.

METHODS. Partially purified sea-urchin kinesin (lanes marked k) was obtained by AMPPNP-microtubule affinity binding, MgATP release, and Biogel A5M chromatography in the absence of MgATP (ref. 12). The kinesin in our standard PMEG buffer<sup>5</sup> was digested with  $\alpha$ -chymotrypsin<sup>12</sup> in the presence (lanes 2, 4, 6, 8) or absence (lanes 1, 3, 5, 7) of microtubules (2 mg ml<sup>-1</sup>) assembled using taxol from purified bovine brain tubulin. Lanes 3 and 4 were incubated with apyrase 50  $\mu$ g ml<sup>-1</sup> to remove residual ATP or ADP; lanes 5 and 6 show digests performed in MgATP (5 mM), whereas 7 and 8 were performed in the presence of Mg AMPPNP (5 mM). Lanes 1 and 2 show digests performed using kinesin from the Biogel column and which presumably contained bound MgADP (ref.

4) (identical results were obtained in parallel digestion reactions performed in the presence of additional MgATP (1 mM) although in the presence of NaCl (0.5 M) microtubules did not protect the 45K peptide). 130K, intact kinesin heavy chain; TUB, tubulin; CT45, the 45K chymotryptic fragment of the kinesin heavy chain; CT25, a minor 25K fragment; DF, dye front.

tubule-nucleotide states and thus resemble the proteolysis of the myosin-head domain, a reaction which is affected by the molecular movements that occur as myosin interacts with nucleotides and actin<sup>16</sup>. We propose therefore that the 45K fragment is a mechanochemical domain on kinesin that contains nucleotide- and microtubule-binding sites<sup>12,13</sup>, and undergoes conformational changes as it interacts with microtubules and nucleotides to generate motile force.

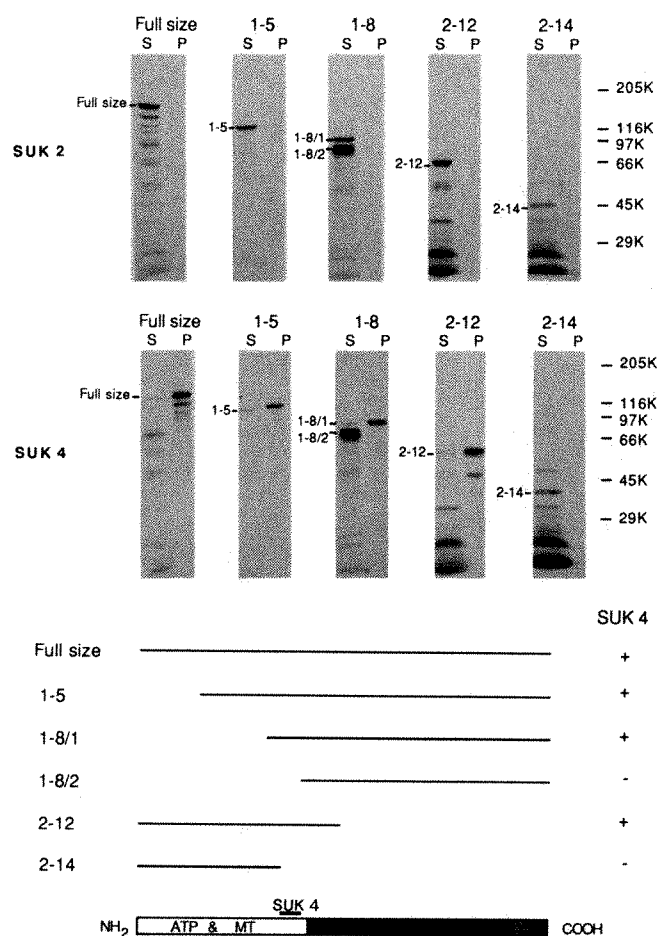

FIG. 2 Localization of the region of kinesin containing the SUK 4 epitope by immunoprecipitations of truncated *Drosophila* kinesin heavy-chain molecules. **a**, Upper panels, autoradiograms of the immunoprecipitation by SUK 2 and SUK 4. Each polypeptide is indicated by a line and its number in the corresponding autoradiogram. S, supernatant; P, pellet. **b**, Schematic representation of the kinesin heavy chain showing the position of the SUK 4 epitope, and the globular N-terminal domain (open box) and the nucleotide (ATP) and microtubule (MT) binding regions defined by previous studies<sup>15</sup>. Translation products that reacted with SUK 4, +. Black region, the  $\alpha$ -helical coiled-coil domain, which ends in a second globular domain (shaded) at the terminus. In this model, SUK 4 lies in residues 320–390 and is near a microtubule binding region.

**METHODS.** Deletions were introduced into the full-length *Drosophila* kinesin heavy-chain cDNA, cloned into pBluescript plasmids (Stratagene) as described previously<sup>14,15</sup> and the truncated products were transcribed, and translated using a reticulocyte lysate system<sup>14,15</sup>. Six translation products were analysed: the full size *Drosophila* kinesin heavy-chain polypeptide consisting of 975 residues; 1-5, which lacks the first 130–170 N-terminal residues; 1-8/1, which lacks ~320 N-terminal residues; 1-8/2, which arises as a result of an internal initiation even in the same cDNA that produces 1-8/1 (ref. 15), and lacks ~390 N-terminal residues; 2-12, which lacks 500 C-terminal residues and 2-14 which lacks 640 C-terminal residues. The lysates containing the expressed, truncated products were incubated with monoclonal antikeratin, SUK 4, which cross-reacts with *Drosophila* kinesin heavy chains<sup>12</sup>, and (as a control) with SUK 2, which reacts with sea urchin but not *Drosophila* kinesin heavy chains<sup>12</sup>. The antibody-antigen complexes were immunoprecipitated using pansorbin *Staphylococcus aureus* cells, and subjected to SDS gel electrophoresis and autoradiography to locate the precipitated polypeptides.

To locate the 45K fragment on the kinesin heavy chain, we first determined the position of the SUK 4 epitope in the protein sequence (Fig. 2). Kinesin heavy-chain molecules carrying deletions of various lengths were produced by expressing truncated versions of the *Drosophila* kinesin heavy-chain gene<sup>14,15</sup>. The binding of SUK 4 to the truncated protein products was assayed by immunoprecipitation: SUK 2, an IgG1 that does not bind to *Drosophila* kinesin<sup>12</sup>, was used as a negative control.

Six translation products were analysed (described fully in ref. 15 and briefly in Fig. 2). As expected, SUK 2 did not immunoprecipitate any of the translation products. The full-size polypeptide (975 residues) and the truncated proteins 1-5, 1-8/1 and 2-12 but not 1-8/2 or 2-14, however, were immunoprecipitated by SUK 4. Significantly, molecules carrying deletions that include residues ~320–390 were not immunoprecipitated by SUK 4. These results suggest therefore that the epitope recognized by SUK 4 lies within the N-terminal third of the kinesin heavy chain, and is probably within residues 320–390. Strikingly, previous studies by Yang *et al.*<sup>15</sup> show that the truncated kinesin heavy chain, 1-8/1, binds to microtubules weakly in sedimentation assays, whereas 1-8/2 does not bind microtubules at all. This indicates that the SUK 4 epitope is located near a region of the kinesin heavy chain that interacts with microtubules.

Yang *et al.*<sup>15</sup> determined the sequence of the *Drosophila* kinesin heavy chain, and predicted that it consists of three structural domains: a globular N-terminal domain; a central  $\alpha$ -helical coiled coil region; and another globular domain at the C-terminal region. In their proposed model, the N-terminal globular domain contains nucleotide- and microtubule-binding sites<sup>15</sup> as well as the SUK 4 epitope (Fig. 2). The SUK 4 epitope and the microtubule- and nucleotide-binding sites are also all localized on the 45K fragment of kinesin, indicating that this 45K peptide corresponds to the globular N-terminal domain predicted from the sequence analysis.

To test this interpretation, we used immunoelectron microscopy to visualize the region of kinesin containing the SUK 4 epitope. The lower panels of Fig. 3a show freeze-etch electron micrographs of individual kinesin molecules as elongated bipolar structures approximately 75 nm in length. Each has two small, symmetrical globular 'heads' (9–10 nm in diameter) at one end of a long stalk (3–5 nm in width), which terminates in an irregular, bipartite 'feathered tail'. The appearance of this tail varies among molecules more than any other ultrastructural feature. One interpretation of these images is shown in Fig. 3b. The upper panels in Fig. 3a show electron micrographs of kinesin molecules decorated with SUK 4. This antibody clearly binds to the globular heads of the molecule, resulting in a marked increase in mass. Typically, this mass is the size of two IgG molecules (diameter 30 nm) and consists of at least six smaller lobes. Because IgG molecules themselves have a tri-lobed appearance<sup>17</sup>, we conclude that each of the two heads binds its own SUK 4 antibody.

Our results indicate that the N-terminal regions of two heavy chains form globular heads on the kinesin molecule (Fig. 3b). We propose that these heads are 'motor' domains undergoing changes in conformation as they interact with nucleotides and microtubules to generate force and motion, and that antibodies such as SUK 4 which bind to these heads can inhibit kinesin-driven motility by interfering with mechanochemical coupling. The junction between the head and the stalk may be flexible, rendering it highly susceptible to proteolysis, as in the case of myosin. In this model, the 45K fragments correspond to detached globular heads that are analogous to myosin subfragment 1(S1). The microtubule-induced ATPase activity of the 45K fragment, like the actin-induced ATPase activity of myosin S1 (ref. 18), is higher than that of the parent enzyme from which it is derived<sup>13</sup>, but whether the mechanism responsible for the elevation of ATPase activity is the same in these two cases remains to be determined.

Kinesin, myosin and dynein thus show striking similarities

FIG. 3 a, Electron micrographs comparing individual sea-urchin kinesin molecules (lower row) with kinesin molecules reacted with the monoclonal antikinesin SUK 4 (upper row). The antibody binds to the two globular heads at the upper ends of the molecules. These represent rotary-shadowed platinum replicas of kinesin molecules (prepared as in Fig. 1 in PMEG buffer without nucleotide) that were adsorbed to microscopic flakes of mica and then freeze-dried by techniques described previously<sup>17</sup>. Magnification 144,000 $\times$ . b, Model of the ultrastructural morphology of individual kinesin molecules. The globular heads, corresponding to the N-terminal domains predicted from the amino-acid sequence<sup>15</sup>, contain the ATP and MT binding sites, and the SUK 4 epitopes. The stalk is thought to consist of an  $\alpha$ -helical coiled coil region (designated by the black area in Fig. 2), which terminates in a heterogeneous, bipartite feathered tail (the shaded C-terminal region in Fig. 2 is thought to interact with additional material to generate structures of the size seen in the micrographs<sup>15</sup>).

in their morphology, consisting of multiple globular mechanochemical heads attached to flexible stalks. The significance of this structural organization, however, is not clearly understood. It is possible that by having more than one head the mechanoenzyme remains attached as it tracks along its cytoskeletal filament with each head undergoing cycles of attachment and detachment. Single-headed myosin-1, however, also seems able to generate sliding between adjacent actin filaments<sup>20</sup>, and to transport beads and organelles along cytoskeletal filaments<sup>21,22</sup>. Johnson<sup>23</sup> has suggested that the flexible segment allows the production of a unidirectional force by mechanoenzymes whose motor domain attaches to its filament and undergoes equal and opposite structural changes during two different steps within the mechanochemical pathway. □

**Note added in proof:** Hirokawa *et al.*<sup>24</sup> have independently arrived at the conclusion that the two small heads on the kinesin molecule bind to microtubules.

**BOTH** the phosphatidylinositol-hydrolysing and the phosphatidylcholine-hydrolysing phospholipases C have been implicated in the generation of second messengers in mammalian cells<sup>1,2</sup>. The phosphatidylcholine-hydrolysing phospholipase C (PLC) from *Bacillus cereus*, a monomeric protein containing 245 amino-acid residues<sup>3</sup>, is similar to some of the corresponding mammalian proteins<sup>4</sup>. This, together with the fact that the bacterial enzyme can mimic the action of mammalian PLC in causing, for example, enhanced prostaglandin biosynthesis<sup>5</sup>, suggests that *B. cereus* PLC can be used as a model for the hitherto poorly characterized mammalian PLCs. We report here the three-dimensional structure of *B. cereus* PLC at 1.5 Å resolution. The enzyme is an all-helix protein belonging to a novel structural class and contains, at least in the crystalline state, three Zn<sup>2+</sup> in the active site. We also present preliminary results from a study at 1.9 Å resolution of the complex between PLC and inorganic phosphate (P<sub>i</sub>) which indicate that the substrate binds directly to the metal ions.

The crystal structure of PLC has been solved at 2.8 Å resolution using multiple isomorphous replacement and solvent flattening<sup>6</sup>, and refined to 1.5 Å through the intermediate resolutions at 2.5, 2.3 and 1.9 Å. The present *R*-factor, using all the data and including 235 water molecules, is 15.7%. The molecular structure is shown in Figs 1 and 2. The crystallographic work, summarized in Table 1, will be published in more detail elsewhere.

The most striking feature of the molecule is the long anti-parallel helix pair formed by helix H and helices F and G, which can be compared with those of citrate synthase<sup>6</sup> and a short helix pair in phospholipases A<sub>2</sub> (ref. 7). Proline 218 in helix H induces a bend between helices H<sub>1</sub> and H<sub>2</sub>. Helix E lies across both this bend and the loop between helices F and G, giving the impression that the long helices are folded round it. The bend in helix B at Trp 43 is probably associated with its packing against the body of the molecule.

‡ Deceased.

FIG. 1 Stereo drawing of the backbone of PLC. Metal ions are shown as filled circles.

Helices A, B, C, D, F and H<sub>2</sub> form a compact arrangement of mixed parallel and antiparallel helices with a predominantly right-handed twist. Helix D runs diagonally within the helix assembly to lie behind the active site at its C-terminal end (Fig. 2). Although PLC seems to be the first enzyme with an all-helix conformation (citrate synthase contains a 13-residue  $\beta$ -sheet segment<sup>41</sup>), several enzymes contain tightly packed helix domains, although there seems to be no common topology (Fig. 2b, I-V).

The N-terminal tryptophan is buried immediately behind the active site and is involved in metal binding (Fig. 3). PLC is probably synthesized as a pro-enzyme with a 14-residue N-terminal extension<sup>3</sup> which could block the active site cleft to render the enzyme inactive and could also alter the metal binding. The last two residues are of the C terminus, which lies at the end of helix H<sub>2</sub>, disordered on the surface of the molecule. All non-helical stretches form external, 'random coil' loops between the helices (Fig. 2).

The amino-acid sequence of PLC shows no significant similarity to those of phospholipases A<sub>2</sub> (ref. 7). There is, however, some structural similarity with bovine<sup>8</sup>, porcine<sup>9</sup> and rattlesnake phospholipase A<sub>2</sub> (ref. 10). Superimposition of the antiparallel (residues 39–58 and 89–108) helix pairs in the latter over helices F and H<sub>2</sub> in PLC results in an approximate overlap of the N-terminal helices in phospholipase A<sub>2</sub> over helix A in PLC and a similar location for the N-terminal residue. In this orientation, the  $\beta$ -sheet region of phospholipase A<sub>2</sub> lies over the E-F loop in PLC. The active sites in the two enzymes, however, are well separated when the molecules are thus superimposed.

PLC is inhibited by P<sub>i</sub> and by monovalent anions<sup>11</sup>, including I<sup>-</sup>. The latter ion blocks the entrance to a cleft 5 Å wide, 8 Å deep and bounded on its external surface by the N-terminal loop, the helix B<sub>2</sub>-helix C loop, the helix D-helix E loop and the N-terminal end of helix E. The essential metal ions<sup>12</sup> lie at the bottom of this cleft and are liganded to residues from these loops and from helices A, B<sub>2</sub>, D and E, thus crosslinking several disparate parts of the protein chain (Fig. 3b). This probably explains the high conformational stability of the holoenzyme relative to the apoenzyme<sup>13</sup>. Furthermore, a 1.9 Å study of P<sub>i</sub>-PLC, now approaching completion (*R*-factor = 19%), shows that P<sub>i</sub> is closely associated to all three metal ions, with its oxygen atoms replacing two of the coordinated water molecules (Fig. 3c). This confirms the identification of the active site and indicates that the catalytic function of the metal ions is similar to that of the metal ions in alkaline phosphatase from *Escherichia coli*<sup>14</sup>, DNA polymerase I (refs 15 and 16) and bovine pancreatic deoxyribonuclease I (ref. 17). There are two distinct groups of residues in the active site: Glu 4, Asp 55, Tyr 56 and Glu 146

form an acidic pocket at one end, whereas Ser 64, Thr 65, Phe 66, Phe 70, Ile 80, Thr 133, Asn 134, Leu 135 and Ser 143 line the remainder. A similar differentiation of active-site residues is discernible in the phospholipases (ref. 18).

Metal bonding and exchange studies<sup>12,19</sup> have indicated the presence of two tightly bound Zn<sup>2+</sup> in active PLC. This was apparently confirmed during the search for heavy-atom derivatives by our identification of two sites where Zn<sup>2+</sup> was replaced with Cd<sup>2+</sup> (ref. 11). The interpretation of electron density maps in what has now proved to be the N-terminal loop region, however, has always been complicated by the presence of high electron density, similar to that of the other two metal ions, which was closely associated with Trp 1, His 14 and Asp 122, and which could not be explained by amino-acid structure. Contact

FIG. 2 a, Schematic drawing of the PLC fold with  $\alpha$ -helices shown as cylinders and metal ions as filled circles. Overall dimensions are 60 × 40 × 30 Å, 66% of residues fold as  $\alpha$ -helix and no  $\beta$ -sheet (predicted<sup>28</sup>, 30–36% helix, 24–30% sheet). Amino acids in helices: A, 12–28; B<sub>1</sub>, 33–44; B<sub>2</sub>, 44–55; C, 85–104; D, 105–125; E, 140–153; F, 171–187; G, 192–202; H<sub>1</sub>, 206–216; and H<sub>2</sub>, 216–243. b, Topology of PLC compared with helix domains in CTS (small domain)<sup>6</sup>, thermolysin (TLN)<sup>29</sup>, beef catalase (BCat)<sup>30</sup> and *Penicillium vitale* catalase (PVCat)<sup>31</sup>. Figures constructed after Levitt and Chothia<sup>32</sup>.

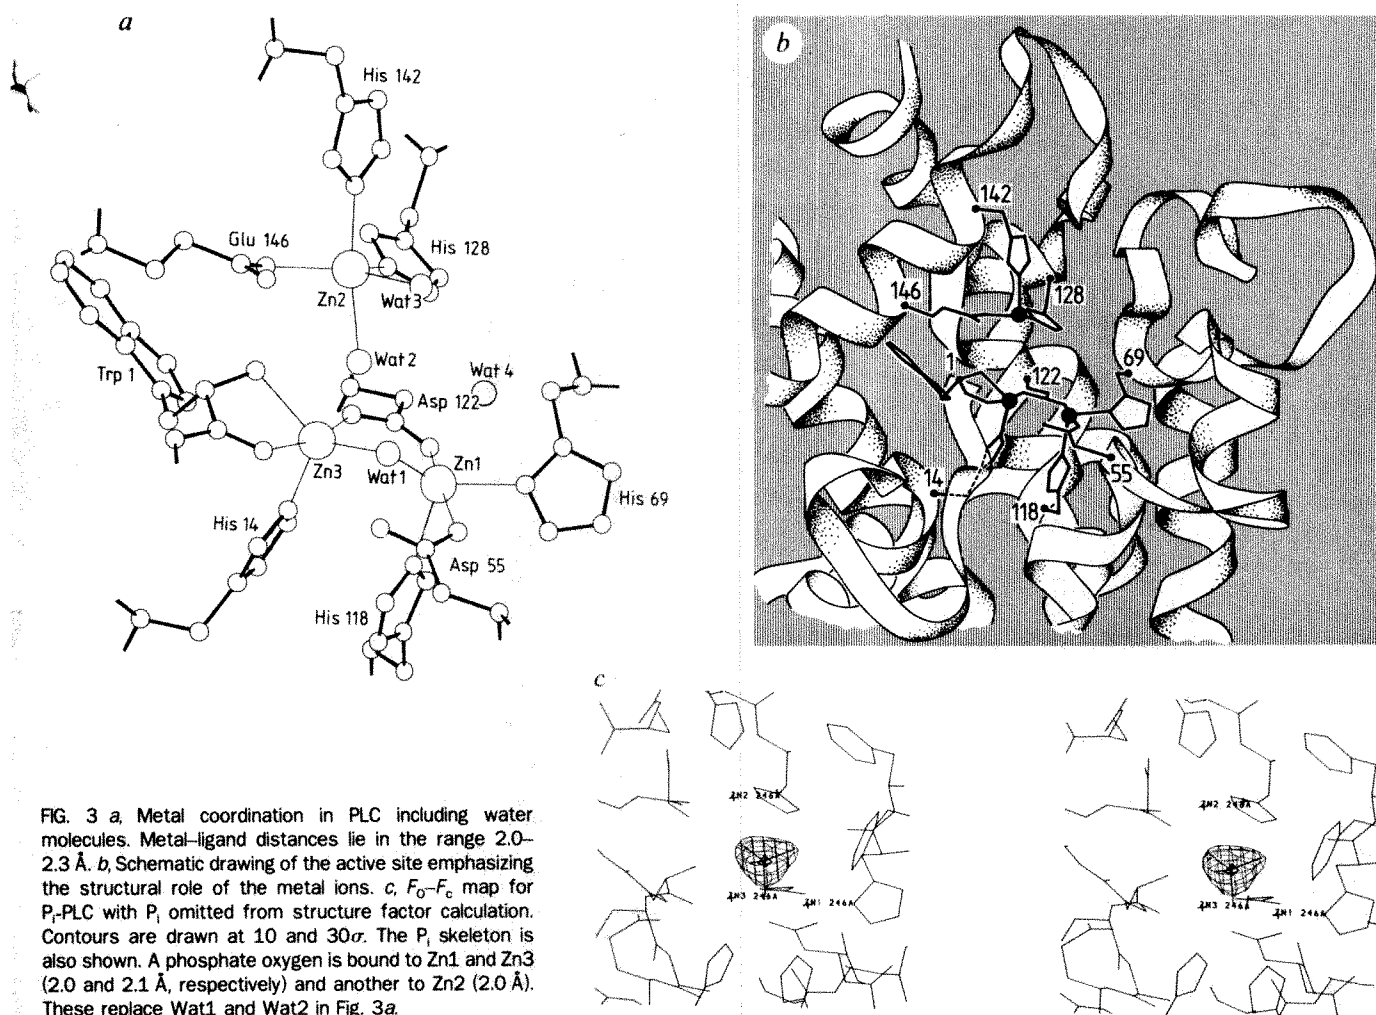

FIG. 3 *a*, Metal coordination in PLC including water molecules. Metal-ligand distances lie in the range 2.0–2.3 Å. *b*, Schematic drawing of the active site emphasizing the structural role of the metal ions. *c*,  $F_0 - F_c$  map for  $P_1$ -PLC with  $P_i$  omitted from structure factor calculation. Contours are drawn at 10 and 30 $\sigma$ . The  $P_i$  skeleton is also shown. A phosphate oxygen is bound to Zn1 and Zn3 (2.0 and 2.1 Å, respectively) and another to Zn2 (2.0 Å). These replace Wat1 and Wat2 in Fig. 3*a*.

TABLE 1 Summary of crystallographic data

Derivative	$N_h$		Resolution limit (Å)

Crystallization: vapour phase diffusion; 5 mg ml<sup>-1</sup> PLC in 35% saturated ammonium sulphate; crystals up to 1.5 mm obtained in 3–4 weeks<sup>33</sup>.

Space group:  $P4_32_12$ ;  $a = 89.93(3)$  Å,  $c = 73.99(4)$  Å; solvent content, 53%;  $M_r = 28,585$ ; 1 molecule per asymmetric unit; data collected on Enraf-Nonius CAD4 diffractometer; native data (1.5 Å) collected on Station 9.6 at Daresbury, U.K.<sup>34</sup>,  $\lambda = 0.88$  Å, 51 film packs, 235,379 reflections merged to 46,061 unique data (99.2% of possible),  $R_{sym}$  for  $I_{hkl} = 0.056$ .

Space group ambiguity was resolved by calculation of SIRAS phases to 4 Å using the anomalous differences of the  $Cd^{2+}$  derivative measured with Cr-K $\alpha$  radiation in  $P4_12_12$  and  $P4_32_12$ ; only the latter gave sensible difference maps for the other derivatives.

Abbreviations:  $N_h$ , number of heavy atom sites;  $F$ , (r.m.s. heavy-atom structure factor)/(r.m.s. lack of closure);  $R_c$ , centric  $R$ -factor ( $\sum(|F_{PH} - F_P| - |F_H|)/\sum|F_{PH} - F_P|$ ) where  $F_{PH}$  and  $F_P$  are the structure factor amplitudes observed for derivative and native respectively, and  $F_H$  is the calculated heavy-atom structure factor amplitude).

Refinement: Konnert-Hendrickson with standard restraints<sup>35</sup>,  $R = 15.7\%$  at 1.5 Å for 45,743 reflections (1.9 Å diffractometer data merged with 1.5 Å synchrotron data) with no  $\sigma F/F$  cutoff and including 235 water molecules. Deviations (r.m.s.) from ideality are: bond distances, 0.021 Å; angle distances, 0.049 Å; planarity 0.014 Å. Luzatti plot<sup>36</sup> corresponds to r.m.s. coordinate error of 0.15 Å. Final refinement and the assignment of water molecules is not yet complete.

\* Graphite-monochromated Cu-K $\alpha$  radiation.

† Cr-K $\alpha$  radiation with vanadium  $\beta$ -filter.

‡ Group scattering factors<sup>37</sup> used for  $PtCl_4^{2-}$ .

distance and charge considerations lead us to conclude that this density is due to a third  $\text{Zn}^{2+}$  (no other metals have been detected in native PLC), which is liganded to the amino and carboxyl groups of Trp 1 to form a five-membered chelate ring similar to that observed in many Zn-amino acid complexes (for example, with aspartic<sup>20</sup> and glutamic<sup>21</sup> acids). The third  $\text{Zn}^{2+}$  is also coordinated to His 14 and Asp 122.

The resulting constellation of metal ions resembles that in alkaline phosphatase from *E. coli*<sup>14</sup>; one of a family of enzymes that have an absolute requirement for  $\text{Zn}^{2+}$  but can bind other metals with retention of activity<sup>22</sup>. The Zn-Zn distances in PLC are similar to those reported for Cd-substituted alkaline phosphatase<sup>14</sup>. Interestingly, the synthesis of both PLC and alkaline phosphatase are P<sub>i</sub>-repressed in *B. cereus* (P. M. Guddal, K. Schulstad, T. Johansen and C.L., unpublished observations) and together represent a P<sub>i</sub> retrieval system for the bacterium. The similarity in the active sites in the two enzymes may therefore be more than coincidental (alkaline phosphatase hydrolyses the product from PLC).

Figure 3a shows the environment of the metal ions. Asp 122 forms a carboxylate bridge between Zn1 and Zn3 (Zn-Zn distance 3.3 Å). Two such bridges occur in myohemerythrin (Fe-Fe, 3.23 Å) (ref. 23) and are probably formed by Asp 51 in AP (ref. 14) and between the metal ions in DNA polymerase I (ref. 16). A molecule of water or OH<sup>-</sup> forms a second bridge between Zn1 and Zn3; again this is similar to the oxide bridge in myohaemerythrin. The coordination of Zn2 resembles that in carboxypeptidase<sup>24</sup>, except that only one of the carboxyl oxygens from Glu 146 is bonded to the metal ion. Metal coordination is completed by two further water molecules so that all three metal ions are approximately trigonal bipyramidal. Histidines 14 and 118 are approximately parallel and are oriented in a manner which resembles charge transfer stacking with a ring-ring distance of 3.7 Å.

Atomic absorption analyses of the metal content of PLC (refs 12, 19 and 25) have consistently indicated two metal ions per mol of PLC and the same is true of a solution state EXAFS study<sup>26</sup>. The metal stoichiometry, however, was calculated from atomic absorption analysis using a relative molecular mass ( $M_r$ ) of 23,000 obtained from calibrated gel filtration<sup>27</sup>. Recalculation using the true  $M_r$  of 28,520 or 28,585, in the case of three Zn ions<sup>3</sup>, gives 2.3 Zn ions per mol PLC, indicating that the third metal site is at least partially occupied even in solution. Furthermore, both the analyses and the EXAFS study were carried out on PLC after an ion-exchange<sup>12,13,19,26</sup> or multi-stage dialysis treatment<sup>25</sup> to remove unbound metal ions, a treatment which would also remove loosely bound metal ions. By contrast, crystallization was performed in the presence of  $\sim 10 \mu\text{M Zn}^{2+}$ . □

**Note added in proof:** PLC has extensive homology with the first two-thirds of the recently published sequence of the alpha-toxin (phospholipase C) of *Clostridium perfringens*<sup>38-40</sup>.

## GUIDE TO AUTHORS

Please follow these guidelines so that your manuscript may be handled expeditiously.

*Nature* is an international journal covering all the sciences. Contributors should therefore bear in mind those readers for whom English is a second language and those who work in other fields. Please write clearly and simply, avoiding unnecessary technical terminology. *Nature's* staff will edit manuscripts to those ends if necessary. Contributors should check their proofs carefully. Because of the competition for space, many of the papers submitted for publication cannot be accepted. For this reason, and because brevity is a great assistance to readers, papers should be as brief as is consistent with intelligibility. Please note that one printed page of *Nature*, without diagrams or other interruptions of the text, has fewer than 1,300 words.

### CATEGORIES OF PAPER

**Review Articles** survey recent developments in a field. Most are commissioned, but suggestions are welcome in the form of a one-page synopsis addressed to the Reviews Coordinator. Length is negotiable in advance but must not exceed six pages of *Nature*.

**Articles** are research reports whose conclusions are of general interest and which are sufficiently rounded to be a substantial advance in understanding. They should not have more than 3,000 words of text or more than six display items (figures and tables) and should not occupy more than five pages of *Nature*.

Articles should be accompanied by a heading of 50–80 words written to advertise their contents in general terms, to which editors will pay particular attention. A heading (printed in italic type) is not an abstract and should not usually contain numbers or measurements. The study should be introduced in more detail in the first two or three paragraphs, which should also briefly summarize its results and implications.

Articles may contain a few subheadings of two or three words. The meaning of the text should not depend on the subheadings, whose function is to break up the text and to point to what follows. There should be fewer than 50 references.

**Letters to Nature** are short reports of outstanding novel findings whose implications are general and important enough to be of interest to those outside the field. Letters should not have more than 1,000 words of text or more than four display items and should not occupy more than two pages of *Nature*. The first paragraph should describe, in not more than 150 words, the origins and chief conclusions of the study. Letters should not have subheadings or more than 30 references.

**Commentary** articles deal with issues in, or arising from, research that are also of interest to readers outside research. Some are commissioned, most are unsolicited. They are normally between one and four pages of *Nature* in length.

**News and Views** articles are intended to inform non-specialist readers about a recently published advance. Suggestions should be made to the News and Views Editor. Illustrations are welcome. Proposals for meeting reports should be agreed in advance.

**Scientific Correspondence** is for the discussion of scientific matters, including contributions published in *Nature*. Priority is given to contributions of less than 500 words and five references. Figures are welcome.

**Submission.** All manuscripts may be submitted to either London or Washington. They should not be addressed to editors by name. Manuscripts or proofs sent by air courier to London should be declared as 'manuscripts' and 'value \$5' to prevent the imposition of import duty and value-added tax (VAT).

### GENERAL

All contributions submitted for publication in *Nature* should conform with these rules.

**Manuscripts** should be typed, double-spaced, with a good-quality printer, on one side of the paper only. Four copies are required, each accompanied by lettered artwork. Four copies of half-tones should be included. Reference lists, figure legends and so on should be on separate sheets, all of which should be double-spaced and numbered. Copies of relevant manuscripts in press or submitted for publication elsewhere should be included, clearly marked as such. Revised and resubmitted manuscripts should also be clearly marked as such and labelled with their reference numbers.

**Titles** should say what the paper is about with the minimum of technical terminology and in fewer than 80 characters. Authors should avoid active verbs, numerical values, abbreviations and punctuation and should include one or two key words for indexing purposes.

**Artwork** should be marked individually and clearly with the author's name, figure number and, when known, manuscript reference number. Original artwork should be unlettered. Ideally, no figure should be larger than 28 by 22 cm. Figures with several parts are permitted only if the parts are closely related, either experimentally or logically. Suggestions for cover illustrations, with captions, are welcome. Original artwork (and one copy of the manuscript) will be returned when a manuscript cannot be published.

**Colour Artwork.** A charge of £500 a page is made for 4-colour figures. Inability to meet these costs will not prevent the publication of essential colour figures if the circumstances are explained.

**Figure legends** must not exceed 300 words and ideally should be much shorter, and should use telegraphic form wherever possible. The figure should be described first, then, briefly, the method. Reference to a full description elsewhere is preferable to a full description. Methods should not be described in detail in the text.

**References** should be numbered sequentially as they appear in the text, followed by those in tables and finally those in the figure legends. Reference numbers apply only to papers published or in the press, and a different number should be given to each paper cited. All other forms of reference (including unreferenced abstracts) should be included in the text as personal communication, manuscript in preparation or preprint (with number and institution where appropriate). Text should not be included in the reference list. References should be abbreviated according to the *World List of Scientific Periodicals* (fourth edition, Butterworth, London, 1963–65). The first and last page numbers should be cited. Reference to books should clearly indicate the publisher and the date and place of publication.

**Abbreviations, symbols, units and Greek letters** should be identified the first time they are used. Acronyms should be avoided as much as possible and, when used, defined. Editors will shorten words if necessary. In case of doubt, SI units should be used.

**Footnotes** should not be used except for changed addresses or to identify the corresponding author if different from the first-named.

**Acknowledgements** should be brief. Grant numbers and contribution numbers are not allowed.

## Journals from Macmillan

### ONCOGENE

**Editors:**

**UK:** John Jenkins and Graham Currie  
Marie Curie Foundation, Oxted, Surrey, UK  
**USA:** E. Premkumar Reddy  
The Wistar Institute, Philadelphia, USA

This journal includes full and detailed papers as well as short communications relevant to all aspects of oncogene research, including the following topics: cellular oncogenes and their mechanisms of activation, structure and functional aspects of their encoded proteins, oncogenes in RNA and DNA tumour viruses, presence of oncogenes in human tumours, relevance and biology, cell cycle control, immortalization, cellular senescence, regulatory genes and "anti-oncogenes", growth factors and receptors.

SAMPLE COPY REQUEST ☐

### Anti-Cancer Drug Design

**Editors:**

**UK:** Stephen Neidle, Cancer Research Campaign  
Biomolecular Structure Research Unit,  
Sutton, Surrey, UK  
**USA:** Stanley T. Crooke, Smith Kline &  
French Laboratories, Philadelphia, USA  
**Japan:** Shigeru Tsukagoshi, Japanese Foundation for  
Cancer Research, Tokyo, Japan

This journal publishes original research papers, reflecting the increasing importance of the tools of structural and molecular biology as well as more classical methodologies.

SAMPLE COPY REQUEST ☐

### APPLIED AND THEORETICAL ELECTROPHORESIS

An official publication of the  
International Electrophoresis Society

**Editor-in-Chief:**

Carl R. Merrill, Bethesda, MD., USA

This new journal aims to facilitate communications between researchers employing electrophoretic methods and those using the methods in a variety of applied settings. Its main goal is prompt publication of:-

- Full length scientific articles
- Peer reviewed newsworthy items from both the academic and industrial worlds in the form of brief reports
- Review articles or supplements on major topics of general interest

SAMPLE COPY REQUEST ☐

#### Sample copy request form

Richard Gedy, Macmillan Press Ltd., Houndmills, Basingstoke, Hampshire, RG21 2XS, UK

Please send me a sample copy of the Journal(s) I have ticked above.

## Peptide and Amino Acid Transport Mechanisms in the Central Nervous System

*Edited by L. Rakic, Professor of Neurobiology and Biochemistry, Belgrade Clinical Centre; David J. Begley, Lecturer, Department of Physiology, King's College London; Hugh Davson, Professor of Physiology, St Thomas Hospital, London and Berislav, Associate Professor, Belgrade University Institute of Medical Physiology*

The way in which the brain regulates its internal environment separately and distinctly from the rest of the body has long generated intense interest and debate. Today, advances are being made at an ever accelerating rate. This volume addresses itself to regulation, within the brain extracellular fluid, of peptide and amino acid levels, particularly those which are known or putative neurotransmitters and neuromodulators. Particular attention is also devoted to the way in which peptides may penetrate the blood-brain barrier or alter its permeability to other solutes. This volume is of vital relevance to anyone studying central nervous system disease, especially the fundamental problem of designing drugs and agents which will penetrate the blood-brain barrier and exert central nervous actions. The relevance to mental health and disease is also unquestioned.

**Contents:** Introduction; H. Davson / Neuropeptide Transport Mechanisms in the Central Nervous System; B.V. Zlokovic et al / Peptides and the Blood-Brain Barrier: Penetration and Modulating Influences; W.D. ## Peripheral Actions of Dopamine

*Edited By Christopher Bell, Department of Physiology, University of Melbourne, Australia and Barry McGrath, Monash University Medical School, Melbourne, Australia*

This book reviews the current state of research in three main areas

concerning the actions and significance of dopamine in the periphery: the source and effects of endogenous dopamine; the classification and distribution of, and the effects of activating, various populations of peripheral dopamine; and the therapeutic significance of dopamine receptor activation and renal disease.

**Contents:** Sources of Circulating Dopamine: A Personal View; J.L. Cucho / Dopamine Storage in Sympathetic Nerves; P. Soares-Da Silva / Neurochemistry of Dopaminergic Nerves; C. Bell, M. Ferguson & T. Petrovic / Release of Dopamine from the Kidney in vivo; P. Hjendahl, T. Bradley & B. Tidgren / Dopamine and Renal Failure; W. Adam / Dopamine and Hypertension; M. Yoshimura & H. ## New Concepts in Depression

*Pierre Fabre Monograph Series, Volume 2*

*Edited by M. Briley, Pierre Fabre Medicament, Castres, France and G. Fillion, Head of Neuroimmunoendocrinology, Pasteur Institute, Paris*

Depression is increasingly seen as an important debilitating neurological condition. This book brings together a timely collection of results and opinions of the major preclinical and clinical researchers in the field of depression. In addition, a number of chapters concentrate on clinical or physiological phenomena associated with depression. The general attitude of the book is one of openness to new ideas several of which are presented here for the first time.

**Contents:** The Contributors / Preface to the Series / Preface / Biochemical Mechanisms in Depression / 5-HT and Depression / Physiological Correlates in Depression / From Experimental Models to Man / Clinical Pharmacology of Depression and Associated Phenomena

## MRC LABORATORY OF MOLECULAR BIOLOGY NMR studies of HIV-1 tat

A 3 year post-doctoral post is available for research into the solution structure of the HIV transactivator protein. This forms part of a wider programme of studies of the structures and functions of HIV proteins in the Laboratory.

Experience in protein structure analysis by 2-D NMR would be preferred, but applicants with experience in other branches of NMR or other forms of structure determination would be considered.

Depending on experience, salary will be on the MRC grade II scales for non-clinical scientific staff (£11,070 to £14,500 per annum). Funds are available for immediate starting dates. Applications including a full curriculum vitae, a list of publications, reprints of no more than three relevant papers, and the names and addresses of 2 professional referees should be sent by 17 April 1989 quoting reference D/NMR to

## ПЕРЕВОДЧИКИ!

### FOR RUSSIAN-ENGLISH SCIENTIFIC AND TECHNICAL TRANSLATIONS

You can follow the latest Soviet research in your field, and supplement your income, by translating in your home on a free-lance basis. If you have good command of English, a good knowledge of Russian, and experience or academic training in a scientific or technical discipline, you may be qualified for our translation program. Immediate openings are available in chemistry, biology, medicine, physics, mathematics, materials science, and biomedical, environmental, and chemical engineering, as well as other fields.

For additional information write or call:

**Translations Editor  
Plenum Publishing Corporation  
233 Spring Street, New York, N.Y. 10013, USA  
Tel: (212) 620-8441**

## FACULTY POSITION IN PHYSIOLOGY

The Department of Physiology at Temple University School of Medicine invites applications for a tenure-track appointment at the ASSISTANT PROFESSOR level. Qualifications for the position include an M.D. or a Ph.D. degree with postdoctoral experience.

The applicant will be expected to develop an active independent research program supported by extramural funding and to contribute to the teaching programs of the department. All areas of research interest will be considered. Salary is commensurate with experience. Applicants should send curriculum vitae, description of research activities and the names and addresses of three references to:

**Dr. James P. Ryan, Chairman of  
Search Committee, Dept. of Physiology,  
TEMPLE UNIVERSITY SCHOOL OF  
MEDICINE, 3401 N. Broad Street,  
Philadelphia, PA 19140.**

Temple is an affirmative action, equal opportunity employer.

## IMAGE ANALYSIS PROJECT RESEARCH FELLOWS (2 positions) A\$31,005 p.a. – A\$45,177 p.a. CSIRO Division of Soils, Canberra, ACT AUSTRALIA

The Division seeks two scientists to work on the development of image analysis methodology and its application to a range of soil investigations. The appointee to Position One (No.A5289) will be expected to work in close collaboration with the CSIRO Division of Information Technology in the development of an image processing system for soil structural analysis. The second appointee (Position No. A3259) will have the background necessary to contribute to the estimation of soil structural properties using stereological and other mathematical techniques. Both candidates will be expected to use techniques developed to investigate soil structural problems associated with crusting, hard-setting and compaction of agricultural soils and other soil related materials.

Both positions are for a five year term; Australian Government superannuation benefits are available.

The appointees will have a PhD or equivalent in an appropriate scientific discipline and experience in image analysis methodology and its application.

Further details can be obtained from Dr. C.J. Chartres (6162) 46 5271 and duty statements and selection criteria from Ms. G. Morgan (6162) 46 5322; Fax (6162) 47 5883.

Applications including a full c.v. and the names of at least two referees should be directed to:

**The Chief  
CSIRO Division of Soils  
GPO Box 639  
Canberra ACT 2601  
Australia**

by April 17th 1989

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER

(W5992)A

### SCIENCE EXHIBIT DEVELOPER

A position is available for someone to research topics in contemporary science, technology, and medicine and develop them into exhibits understandable and relevant to the general public. As part of a staff team, which conceives the theme and organization of the topics, the exhibit developer will contribute to the design presentation, originate and evaluate exhibit content, prototype, and test exhibit ideas. The developer will also utilize technologies, such as computers, to enhance the presentation of science information.

Requirements: A.B. or higher degree in a science or related field. Would be helpful to have excellent writing skills, experience in public education and project management, and skills to use computers and other kinds of exhibit equipment. Candidates should be imaginative, self-motivated, with hands-on laboratory and/or workshop experience. Send letter of application, CV, and three letters of recommendation to:

**Director of Human Resources,  
Museum of Science and Industry,  
57th Street and Lake Shore Drive,  
Chicago,  
IL 60637-2093. AA/EOE. (NW3495)A**

### UNITED MEDICAL AND DENTAL SCHOOLS of Guy's & St Thomas's Hospitals RESEARCH ASSISTANT

required in the Renal Unit of the Clinical Science Laboratories at our Guy's Campus (close London Bridge BR and London Transport) to work on a project involving molecular HLA mapping in patients with auto-immune disease. This is a collaborative project with a basic science laboratory in Oxford, to which occasional travel may be required. Duties include general laboratory responsibilities. Previous experience with DNA/RNA molecular biology techniques is desirable. Salary scale: £11,515 - £13,330 inclusive according to age, qualifications and experience. Appointment is for one year in the first instance. For further information, please telephone Dr. S. Sacks on 01-407 7600 extn 2784. To apply, please write with full CV and names and addresses of two referees to: **The Personnel Officer, UMDS, St Thomas's Campus, Lambeth Palace Road, London SE1 7EH, quoting Reference No. G/CSL/324. Closing date: 7 April 1989.** (8799)A

### UNIVERSITY OF SOUTHAMPTON Lymphoma Research Unit, Tenovus Laboratory Southampton General Hospital, Southampton, SO9 4XY

A post is currently available in the Tenovus Research laboratory for a

#### Research Assistant

to help establish culture facilities for the bulk production of monoclonal antibodies using hollow-fibre technology. The main objective of this project is to provide clinical grade material to a team of scientists and clinicians working on the production of novel antibody derivatives for the treatment of human lymphoma. Experience in cell culture technique and immunoassays would be desirable but not essential. The position is funded for three years and carries a salary, according to age and experience, on the University 1B scale for research staff (£8,675 - £11,680 pa, under review). For further details concerning the project contact Dr M Glennie at the Tenovus Research Laboratory (0703) 777222 Ext. 3230.

Applications including a C.V. and the names and addresses of two referees, to **Ms J A Doyle, Staffing Department, University of Southampton, Highfield, Southampton, SO9 5NH.**

Please quote reference 283/JAD/jm.  
(8794)A

### CHESTER BEATTY LABORATORIES INSTITUTE OF CANCER RESEARCH

#### Section of Cell and Molecular Biology A Postdoctoral Position

is available to work with Dr. Alan Hall at the Chester Beatty Laboratories to examine the function of the ras GTPase activating protein, GAP. A wide range of techniques will be used to study the biochemical and biological consequences of the interaction between ras and GAP. The work is part of a new collaborative venture with The Wellcome Foundation and the successful candidate will be able to make use of the excellent research facilities at the Chester Beatty Laboratories and at The Wellcome Research Laboratories at Beckenham.

Salary in the range £13130 to £15950.

Applicants are advised that smoking is prohibited in the majority of the Institute's premises.

To apply, please submit a Curriculum Vitae, in duplicate, with the names and addresses of two referees to **The Personnel Officer, the Institute of Cancer Research, 17a Onslow Gardens, London SW7 3AL** quoting reference number 3.89.S.N.85. (8815)A

## RESEARCH FELLOW GEOPHYSICAL FLUID DYNAMICS

**A\$31,003 - A\$45,177**

**DIVISION OF ATMOSPHERIC RESEARCH,  
ASPENDALE, VICTORIA, AUSTRALIA.**

**FIELD:** Strait flows and Coastal Current Dynamics.

**THE DIVISION:** The Division of Atmospheric Research conducts strategic and applied research into problems concerning the physics, dynamics and chemistry of the atmosphere and ocean system.

**THE JOB:** The appointee will undertake research into the character of the stratified Bass Strait overflow and its consequences for the Tasman Sea circulation and non-linear coastal hydraulics generally, using laboratory and theoretical techniques. Studies of coastal systems and boundary currents affected by both stratified or Rossby-wave hydraulics are planned as an extension of this work.

**THE PERSON:** Applicants should possess a Ph.D degree or equivalent qualification in geophysical fluid dynamics, together with experience in or an aptitude for laboratory studies.

**CONDITIONS:** Appointment will be for a term of 3 years, with Australian Government superannuation benefits available.

**MORE INFORMATION:** Prospective applicants are invited to contact Dr. Peter Baines on (0011-61-3) 586 7651, fax (0011-61-3) 586 7600, for further information. Dr. Baines can also provide a copy of the duty statement and selection criteria.

**APPLICATIONS:** Applications should be submitted by 14 April 1989 and should quote reference number A1848. They should be framed against the selection criteria and should provide relevant personal particulars, including details of qualifications and experience. Applicants should nominate at least two professional referees and address their application to:

**The Chief,  
CSIRO Division of  
Atmospheric Research,  
Private Mail Bag No. 1,  
Mordialloc, Victoria, Australia 3195.**

**CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER (W5993)A**  
AT 89/09a

### UNIVERSITY OF TASMANIA

Applications are invited from suitably qualified men or women for the following position.

#### CHAIR OF PHYSIOLOGY (Ref. 42/89)

Applications are invited for appointment to the Chair of Physiology and Head of Physiology, a position which has been vacant since the retirement of Professor A. F. Cobbold.

The Department of Physiology includes Pharmacology and is an integral part of the Faculty of Medicine. It is also a member of the newly-formed School of Biological Sciences.

The Department has responsibility for the undergraduate teaching of physiology to medical and pharmacy students and pharmacology to medical students. Postgraduate degree courses in Master of Medical Sciences and Doctor of Philosophy are offered within both the physiology and pharmacology disciplines.

Expressions of interest are welcome from applicants with a high research standing, wide experience in postgraduate supervision and an experimental orientation towards any area of physiology and/or pharmacology. The successful applicant will be expected to provide teaching, research and administrative leadership within the Department.

An information booklet containing details about the post, the Faculty of Medicine and the University is available from the Staff Office.

Enquiries about academic aspects of the post should be directed to the Head of the Department of Physiology, Dr. L. J. McLeod (tel. 002.202678).

The Professorial salary effective from 15 May is \$63,919 with a clinical loading of between \$5,690-\$11,366 for a medically qualified appointee. The appropriate loading depends on the extent of clinical responsibilities undertaken.

Applications close 31 May 1989.

Position information and application forms available from the Staff Office Secretary, tel. (002) 202013. Applications quoting ref. should be sent to the **Staff Officer, University of Tasmania, G.P.O. Box 252C, Hobart, Tasmania, Australia, 7001.**

**THE UNIVERSITY IS AN EQUAL OPPORTUNITY EMPLOYER (W6000)A**

# UNIVERSITY OF ABERDEEN

## New Academic Appointments Scheme

Applications are invited for the following new posts under the terms of the UGC Scheme. The intention is to recruit younger academic staff and it is anticipated that initial appointment will be to the Lecturer Grade A Scale (£9260 - £14500). The University expects to be able to offer lectureships in the following areas from October 1989/90:

### Forestry/Plant Science

**Ref. JA/035** Research is expected to concentrate on host identification and infection in fungal diseases of trees. Applicants should have a background in either Forestry or Plant Science with an interest in the other area.

### Biochemistry

**Ref. JA/036** Research will concentrate on the area of macromolecular biochemistry with special reference to the nucleic acid: protein interface in eukaryotic systems.

### Bio-Medical Physics/Computing Science

**Ref. LW/006** Complementing current research activities in both Departments, the research specialisation will be "The Application of Parallel Systems to Vision/Medical Imaging".

### Biotechnology

**Ref. JA/039** Applicants for these 2 posts should have primary training in recombinant DNA technology with research interests in one of the following areas: microbial plant pathogenesis (bacterial/fungal); molecular parasitology or insect molecular biology; control of gene expression in lower eukaryotes; or molecular immunology.

### Chemistry

**Ref. JA/037** Applicants should have research interests in any branch of physical chemistry. Special consideration will be given to those with expertise in the area of spectroscopy/molecular structure, kinetics or polymer science.

### History/History of Art

**Ref. JA/038** The appointee will specialise in the late medieval/early modern European period.

### Spanish

**Ref. JA/041** Applicants should have research interests in Latin-American and modern Spanish literature. An interest in language-teaching methodology will be a strong additional qualification.

### Physiology

**Ref. LW/008** Applicants should have a research interest in neuroscience, particularly in autonomic control, and experience in modern electrophysiological and molecular probe techniques.

### Zoology

**Ref. LW/009** Applicants should have extensive research experience in the use of standard respirometry and stable isotope techniques, particularly doubly-labelled water, with a view to their application in the study of marine resources and the energetics of marine top predators.

### Geography

**Ref. JA/040** Research in the field of Remote Sensing, with a subsidiary specialism in Geographical Information Systems. Involvement in a group research programme in the area of mapping science. Teaching will relate mainly to the established MSc course in Environmental Remote Sensing.

### Public Law

**Ref. LW/007** Applicants should have a particular interest in European Law.

### Divinity

**Ref. LW/010** Applicants should have a research interest in one or more of the following areas: Third World issues, business and medical ethics, mission and ecumenism.

Further particulars may be obtained from the Personnel Office, University of Aberdeen, Regent Walk, Aberdeen, AB9 1FX (Telephone 0224 273500) to whom applications (2 copies) should be returned by 21 April 1989. Please quote the appropriate reference number.

(8788)A

## University of Glasgow Department of Physics and Astronomy Experimental Particle Physics

### KELVIN CHAIR

Applications are invited from experimental particle physicists for appointment to the Kelvin Chair in the Department of Physics and Astronomy. The appointment will be tenable from 1st October 1989 or as soon as possible thereafter. The successful candidate will have an outstanding research record, have demonstrated leadership abilities and will be expected to carry out research in experimental particle physics and to contribute to undergraduate and postgraduate teaching in physics.

Further particulars may be obtained from the Academic Personnel Office, University of Glasgow, Glasgow, G12 8QQ (Tel. 041 339 8855) where applications (3 copies; 1 copy in the case of overseas applicants) giving the names and addresses of three referees should be lodged on or before 2nd May, 1989.

In reply please quote Ref. No. 6506M. (8792)A

## UNIVERSITY OF AUCKLAND New Zealand

DEPARTMENT OF CELLULAR AND  
MOLECULAR BIOLOGY

### POSTDOCTORAL POSITION

To study the effects of cyclic AMP on growth and differentiation of tumour cells, particularly effects on phosphatidylinositol metabolism and possible involvement of oncogenes. Experience in these areas would be advantageous. The position is available for 2 years and includes a return airfare. For further information contact Professor Ray Ralph, Department of Cellular and Molecular Biology, University of Auckland, Private Bag, Auckland, New Zealand. Tel: 64 9 737 999, Fax: 64 9 31 618. (W5995)A

## ST GEORGE'S HOSPITAL MEDICAL SCHOOL (University of London) Postdoctoral Pharmacologist

Applications are invited for a postdoctoral research worker for a three year appointment in the Department of Physiology. The project involves investigating the receptor mechanisms which control airway secretion. Salary will be on the RIA scale (£11,515 - £17,370, including London allowance) depending on qualifications and experience.

### Research Technician

Applications are invited for a post as research technician, grade 5, for a three year appointment to assist in the above project. Salary up to £9,088 (including London allowance).

Application forms and further details from the Personnel Office, St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE (01-672 9944 ext 56020).

Closing date 14 April 1989. Quote reference 40/89.

(8797)A

## UNIVERSITY OF CAMBRIDGE University Lecturer in Immunology in the Department of Pathology

University Lecturer in Immunology to take up appointment on 1st October 1989, or as soon as possible thereafter. The successful candidate will be expected to have an interest in basic mechanisms in Cellular and Molecular Immunology and to offer a research programme complementary to those ongoing in the Division and to contribute to the Departmental teaching.

Salary ranges: £13,365 to £20,615.

Further information and application form from:

**The Secretary, Appointments Committee,  
19 Trumpington Street, Cambridge, CB2 1QA**  
(Tel: 0223 334999 Fax: 0223 332355).

Closing Date: 12 May 1989 (8817)A

## The Center for Climate Research of Lamont-Doherty Geological Observatory

The Center for Climate Research of Lamont-Doherty Geological Observatory has received a gift to be used for construction and exercise of a global ocean simulation model for climate change research. The model will test scenarios of natural variability and human impacts, including those evident in the paleoclimate record.

*We will create an outstanding scientific group by adding the following personnel.\**

■ **Ocean Modeler.** Either a numerical analyst using these skills to solve problems in ocean physics, or an oceanographer well versed in numerical techniques. An ocean model suitable for climate studies must be able to withstand a confrontation with observational data: physical, chemical, biological, and paleo — though not necessarily on the first try. The arrogance to blame discrepancies on the forcing or verification data can be a plus, but only if it can be rigorously justified and is accompanied by a suggested solution. As you see present ocean models, what are their principal problems? Your solutions?

■ **Empirical Studies** of the global ocean relating to climate. An oceanographer or meteorologist whose primary interest is data, but who is enthusiastic about using data in conjunction with numerical models. Sufficiently interested in nuts and bolts issues to direct an effort to create, manage, and provide the tools to manipulate the oceanographic and atmospheric database needed to initialize, drive, and verify ocean models. What questions do you think can be answered with the data on hand?

■ **El Niño Forecaster.** A meteorologist or oceanographer to assume the leadership of our ongoing ocean-atmosphere dynamical prediction activity. The opportunity to choose the direction of future research, including an expansion to climate phenomena other than ENSO. Skills in statistical methods and empirical studies would best complement our strengths in theory and modeling.

■ **Scientific Programmer.** Builder/Keeper of the global ocean model. Experience with large scale numerical models and supercomputers essential.

Applications should be sent to: Office of the Director  
**Lamont-Doherty Geological Observatory of Columbia University**  
Route 9W / Palisades, NY 10964  
*Columbia University is an Equal Opportunity/Affirmative Action Employer*

### POST DOCTORAL FELLOWSHIPS:

#### ■ Ocean-Atmosphere Interaction.

To study and model the Planetary Boundary Layer or the Ocean Mixed Layer. We are especially interested in the tropics and high latitudes.

#### ■ Physical or Chemical Oceanography.

To diagnose model problems by intensive study of a specific physical oceanographic problem crucial to an understanding of the global ocean circulation. What problem would you like to work on?

#### ■ Ocean-Atmosphere Interaction.

To build on present dynamical modeling studies of ENSO. Possibilities include extension of the model to the global tropics; study of tropical flood/drought, e.g. in Brazil, Africa, India; analysis of related observational data.

*\*(Ph.D. or equivalent experience required. Level of appointment will be commensurate with education and experience.)*

(NW3489)A

## SEARCH RE-OPENED TENURE-TRACK FACULTY POSITION IN PALEOCEANOGRAPHY

The Institute of Marine Science, University of Alaska Fairbanks, has re-opened its search for a tenure-track faculty member in paleoceanography. The appointment will be with the Institute of Marine Science in the recently organized School of Fisheries and Ocean Sciences and involves research, graduate-level instruction, and direction of graduate student research. The Institute of Marine Science has a faculty of 24 and about 40 graduate students at the M.S. and Ph.D. level. Institute faculty are involved in a variety of research programs emphasizing arctic and sub-arctic seas and are actively planning university-wide programs addressing global change.

We seek a colleague committed to collaborative work in paleoceanography in a broad sense and welcome applicants bringing modern approaches from geology, physics, chemistry or biology. The appointee must hold a Ph.D. and will be responsible for developing an active research program in paleoceanography. We anticipate filling this position at the assistant professor level, but will consider a more senior appointment in exceptional cases.

Applicants should send (by April 30, 1989) a statement of research interests, a curriculum vitae, and the names and addresses of three references to:

**William S. Reeburgh**  
**Chair, Paleoceanographer Search Committee**  
**C/O Director's Office**  
**Institute of Marine Science**  
**University of Alaska Fairbanks**  
**Fairbanks, Alaska 99775-1080**

Applications of finalists may be subject to public disclosure. Persons hired must comply with the new employment provisions of the Federal Immigration Reporting Act. The University of Alaska is an Equal Opportunity/Affirmative Action Employer, educational institution, and could become a year-round paradise with a little global warming.

(NW3470)A

## UNIVERSITY OF NEWCASTLE UPON TYNE THE MEDICAL SCHOOL

### Lecturer in Environmental Toxicology

Applications are invited for a new post of Lecturer in Environmental Toxicology in the Division of Environmental and Occupational Medicine, which we expect to be able to fill under a new UGC initiative. A suitable candidate would have a research background in chemistry or other life science and a higher degree and be interested in the application and development of analytical techniques for monitoring toxic compounds in the environment and man. A teaching commitment would be expected on an established MSc course in Occupational Hygiene and a new course in Human Toxicology. Participation in the provision of a specialist analytical service to industry through the Medical School Company would be encouraged.

Closing date: 14th April 1989.

### DEPARTMENT OF PHYSICS

#### Lecturer in Computational Solid State Physics

Applications are invited for the above post which we expect to be able to fill from October 1989 under a new UGC initiative. Current research efforts in the field concentrate on electronic structure, optical and structural properties of perfect and imperfect solids, with particular emphasis on low dimensional semiconductor microstructures. The computing facilities available on the campus include Amdahl 5860, Encore Multimax and Gould NPI with vector processing facility. There are collaborative contacts with prestigious research laboratories engaged in related experimental work. This research programme enjoys generous support from funding agencies in the UK, USA and European Community. Applicants should be able to demonstrate significant research and achievement in a closely related or complementary research activity.

Closing date: 21st April 1989.

#### FOR BOTH POSTS:

Salary will be at an appropriate point on either Lecturer Grade A: £9,260-£14,500 or Grade B: £15,105-£19,310 p.a. according to qualifications and experience. This appointment is viewed as an opportunity for candidates in the early stages of their careers.

Further particulars may be obtained from the **Senior Assistant Registrar (Establishments), The University, 6 Kensington Terrace, Newcastle upon Tyne NE1 7RU** with whom applications (3 copies) with the names and addresses of three referees.

(8827)A

# RESEARCH FELLOW (APPLIED CLIMATOLOGIST)

\$A31,003-\$A45,177

DIVISION OF ATMOSPHERIC RESEARCH  
ASPENDALE, VICTORIA, AUSTRALIA

**THE PROGRAM:** The Division of Atmospheric Research has a major program investigating regional climate change and its impacts, with special reference to the greenhouse effect.

**THE JOB:** To undertake research into the potential impact of the greenhouse effect at a local and regional level, using the best available scientific information from climate modelling and other sources, with a view to providing state-of-the-science advice to local and regional authorities and industries. Liaison with other scientists, specialists and potential users of information across a range of disciplines will be required.

**THE PERSON:** Applicants should possess a Ph.D. degree or equivalent in meteorology or the atmospheric sciences, and preferably, a strong background of experience in applied climatology, computing, and interaction with industries and public authorities. Consideration could be given to the appointment of an outstanding applicant at a higher level.

Maturity of judgement, an ability to write succinct and well-documented reports, and to communicate across disciplines and to the media is essential. The appointee will be located at Aspendale, but must be prepared to travel interstate.

**CONDITIONS:** Appointment will be for a term of 4 years, with the possibility of a further term. Australian Government superannuation benefits are available.

**MORE INFORMATION:** Prospective applicants are invited to contact Dr A. Barrie Pittock on (0011-61-3) 586 7527, fax (0011-61-3) 586 7600, or telex AA34463, who can provide a copy of the duty statement and selection criteria.

**APPLICATIONS:** Applications should be submitted by 14 April 1989 and should quote reference number A1839. They should be framed against the selection criteria and should provide relevant personal particulars, including qualifications, transcripts of tertiary results and experience. Applicants should nominate at least two professional referees and address their application to:

The Chief,  
CSIRO Division of  
Atmospheric Research,  
Private Mail Bag No. 1,  
Mordialloc, Victoria, Australia 3195.

CSIRO

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER

AT 89/088

## THE LONDON HOSPITAL MEDICAL COLLEGE (University of London) RESEARCH ASSISTANT (1B) The Medical Unit

Research Assistant required to join established molecular biology group working on the immunogenetics of kidney disease. Would preferably suite a graduate in biochemistry, genetics, immunology or microbiology. Previous experience of molecular biology techniques would be an advantage. Salary £8,675 plus £1,650 London Weighting.

Application form and job description available from Dr G A Hitman, Assistant Director, Medical Unit, The London Hospital, Whitechapel, London E1 1BB (Tel: 01-377 7111).

Closing date: within 2 weeks of the date of this advertisement. (8802)A

## M.D. ANDERSON CANCER CENTER

Postdoctoral and Research Associate Positions, M.D. Anderson Cancer Center, Department of Clinical Immunology and Biological Therapy in the Laboratory of Cytokine Research. Identification of new cytokines (growth inhibitors and stimulators) produced by the immune system and involved in tumor cell surveillance. Interested in understanding the role of oncogenes, signal-transduction and growth factors in the mechanism of tumor cell resistance to these cytokines. Experience in cell biology, protein purification or gene cloning; background in cellular immunology and/or tumor biology is desirable. Ph.D. and/or M.S./B.S.

Please send C.V. with the names of three references to: Dr. Bharat B. Aggarwal, Chief, Section of Cytokine Research, M.D. Anderson Cancer Center, Department of Clinical Immunology and Biological Therapy, 1515 Holcombe Boulevard, Houston, Texas 77030.

EOE/AA

(NW3479)A

## NATIONAL INSTITUTE FOR MEDICAL RESEARCH GENES AND CELLULAR CONTROLS GROUP RESEARCH OFFICER/SENIOR RESEARCH OFFICER

Applications are invited for a Research Officer/Senior position tenable in the laboratory of Eukaryotic Molecular Genetics (Head: Dr P W J Rigby). The person appointed will work with Dr Rigby on the construction of retrovirus vectors and their use in analysing gene expression in cultured embryonic stem cells in embryos, and on other projects concerned with the regulation of gene expression in tumour and embryonic cells. Previous experience in recombinant DNA technology is essential; experience with mammalian cell culture, virology or embryology would be advantageous.

Qualifications could include a degree, HTEC or similar, but enthusiasm, ability to accept responsibility and work independently are more important.

Entry to the Research Officer grade is subject to two years relevant experience after graduation. Applicants with less than two years experience will initially be appointed to the Trainee Research Officer grade. Salary is in the range of £8,172 (for immediate graduates) to £14,646 per annum inclusive of London Weighting.

The Institute is situated in pleasant rural surroundings and offers good sports, recreational and social facilities. Please telephone for an application form on 01-959-3666, extension 2270, or write to Mr N J Bowry, Personnel Officer, NIMR, The Ridgeway, Mill Hill, NW7 1AA quoting reference: GEKG/0368.

The closing date for completed applications will be 21st April 1989

An Equal Opportunities Employer. (8814)A

MRC

## INSTITUTE OF ZOOLOGY ZOOLOGICAL SOCIETY OF LONDON

**RESEARCH ASSOCIATESHIP** (Ref: ADB/NLCM). A postdoctoral developmental biologist/molecular geneticist is required in the Developmental Biology Unit to join a team investigating endocrine functions of the primate blastocyst, in particular the interaction between inner cell mass tissue and trophoblast in the secretion of chorionic gonadotrophin. The post involves close collaboration with the Molecular Genetics Unit and with others studying the endocrinology of early gestation in the marmoset. This position would suit a developmental biologist wishing to apply molecular genetic techniques to problems of early embryonic development, or a molecular geneticist wishing to investigate this area. The post which is funded by an MRC/AFRC Programme Grant, is for 3 years in the first instance, with the possibility of extension for a further 2 years. Salary in the range of £11,448 - £13,263 including London Weighting, according to age and experience. For further details please contact Professor A P F Flint, Institute of Zoology, Zoological Society of London, Regent's Park, London NW1 4RY (telephone: 01-722 3333), to whom written applications, including a detailed CV and the names of three referees, should be sent not later than 21 April, 1989.

(8786)A

## JUNIOR INVESTIGATORS RESEARCH ASSOCIATESHIPS POSTDOCTORAL FELLOWSHIPS

### UNIVERSITY OF OTTAWA HEART INSTITUTE

The newly established University of Ottawa Heart Institute Research Centre has openings for the above positions in the field of receptors, signal transduction, regulation of gene expression as well as the biochemistry of cardiac and connective muscle tissue.

The centre offers excellent new physical facilities as well as the possibility of direct interaction with the clinical staff.

*In accordance with Canadian Immigration requirements, priority will be given to junior investigators and research associates who are Canadian citizens or landed immigrants in Canada.*

Submit curriculum vitae, statement of research interests, and the names, addresses, and telephone numbers of three references to: Dr. Adolfo J. de Bold, Director of Research, University of Ottawa Heart Institute, 1053 Carling Avenue, Ottawa, Canada, K1Y 4E9. (NW3492)A

**HARVARD MEDICAL SCHOOL  
MASSACHUSETTS GENERAL —  
McLEAN HOSPITALS**

**CHIEF OF PSYCHIATRY**

Harvard Medical School and the Department of Psychiatry at the McLean and Massachusetts General Hospitals are seeking an internationally renowned psychiatrist who possesses the clinical experience, administrative skills and management competence necessary to oversee a complex network of inpatient and outpatient services. The candidate should be a noted investigator and teacher with broad experience and skills as an academic psychiatrist who meets the criteria for a tenured professorship at HMS. He/She should be committed to a major research program aimed at understanding the cause, prevention and treatment of mental illness. The individual selected will hold titles of Professor of Psychiatry and Head of the Massachusetts General Hospital-McLean Hospital Department of Psychiatry at the Harvard Medical School; Chief of the Psychiatric Services at the Massachusetts General Hospital; Psychiatrist-in-Chief and General Director of the McLean Hospital. Reply with curriculum vitae to **Dr. Arthur Kleinman, William James Hall 330, 33 Kirkland Street, Harvard University, Cambridge, MA 02138.**

*Harvard Medical School, Massachusetts General Hospital, and McLean Hospital are Affirmative Action/Equal Opportunity Employers.* (NW3490)A

**STATE OF KUWAIT  
KUWAIT UNIVERSITY  
COLLEGE OF SCIENCE**

The Kuwait University College of Science, Dept. of Botany & Microbiology invites applications for posts of Professor, Associate Professor and Assistant Professor for the academic year 1989/90, tenable February 10, 1990 in the following disciplines:—

- **Plant Breeding**
- **Microbial Physiology**
- **Agriculture & Economic Botany.**

The language of instruction of the College of Science is English. The method of teaching is based on the credit hour system. Applicants must hold the Ph.D. or its equivalent at the time of application.

All applications together with a non-returnable copy of academic Qualifications and representative publications should be sent by registered post directly to:—

Dean  
College of Science  
P.O. Box 5969  
13060 Safat  
Kuwait

*All applications must be received by August 31, 1989.* (W5997)A

**GBF Gesellschaft für Biotechnologische Forschung mbH,** Braunschweig, FR Germany — a government supported Research Institute of Biotechnology — offers a

**Postdoctoral Position**

The appointed scientist will join an international collaborative project involving Dr. J.E.G. McCarthy (GBF), Dr. M.F. Tuite (Kent Univ., England) and Dr. A.J.P. Brown (Glasgow Univ., Scotland), financed by the Commission of the European Communities.

The position is available for three years from May 1989. Applications from candidates with experience in (yeast) molecular genetics should be addressed (referring to ref. no. 40/89) to the Personnel Dept., GBF, Mascheroder Weg 1, D-3300 Braunschweig, FRG. Please include a complete c.v., list of publications, details of research activities to date and the names and addresses of three referees. Informal enquiries can be made to Dr. J.E.G. McCarthy (Tel. 0531/6181-430).

(W5999)A

# Pharmaceutical Research

We are one of the largest French pharmaceutical firms recognized internationally for the efficiency of our achievements in research. We are currently establishing new research initiatives and are recruiting scientists with experience in drug discovery for the positions of Research Department Director and Project Leader in the following therapeutic specialities.

## Hæmobiology

**Haematologists knowledgeable in the mechanisms of coagulation and the interaction of blood elements with the vascular wall relevant to the aetiology of atherosclerosis.**

## Phlebobiology

**Candidates highly competent in haemodynamics, vascular inflammation and haemostasis.**

Candidates must have a Ph.D. or equivalent degree and have extensive experience of pharmacological models relevant to each speciality.

The successful candidates will be inventors, combining the qualities of scientist and industrialist, and will be capable of applying their ideas to the discovery of new compounds.

Experience in the pharmaceutical industry is desirable and the ability to interact constructively with therapeutic chemists is essential.

Our research centre is located in suburban Paris.

Please forward a hand-written letter, curriculum vitae and photograph to Media-System, 6 impasse des Deux Cousins, 75849 Paris cedex 17 - France.

Please quote ref. 49464.

(W5998)A

## A LINK PROGRAMME

### PROGRAMME MANAGER

#### COLLABORATIVE RESEARCH IN BIOCHEMICAL ENGINEERING

A major LINK Programme of Collaborative research in Biochemical Engineering is to be launched in the spring of 1989. It will be funded by UK industry, DTI and SERC, and will comprise many inter-related projects, involving UK firms and UK research organisations, in collaborative research.

It is necessary to appoint a Programme Manager, who will have a major role in establishing and managing the Programme. This role will involve, inter alia, stimulating collaborative proposals and coordinating the activities of the research groups involved. He/she would also be responsible for ensuring effective interaction between all the funding partners. Candidates should preferably have experience of equipment and process development in the biotechnology field.

This full-time, fixed term appointment will be for 3 years initially, with possible extension, and location will be by arrangement, although considerable travel will be required. Salary is negotiable. Secondment from industry or academia would be considered.

Please send CV and statement describing applicant's suitability for the post by 20th April 1989 to:

Mr R A Frewin, (8826)A  
Branch 3,  
Engineering Markets Division,  
Room 365, Ashdown House,  
123 Victoria Street,  
London SW1E 6RB

The Science and Engineering Research Council

#### University of Geneva announces an opening for a position of a FULL PROFESSOR in

#### COMPUTATIONAL CONDENSED MATTER PHYSICS

The new professor will have the responsibility for research and teaching in computational condensed matter physics. He will in particular have the task to develop the research activities of the "Institut Romand de Recherches Numériques en physique des Matériaux" (IRRMA) situated at the campus of the "Ecole Polytechnique Fédérale de Lausanne". He will assume the direction of this Institute for a certain number of years and it is also expected that he actively participates in the scientific and academic life of the University of Geneva.

The applicant should have a Ph D in physics or an equivalent degree. Experience in teaching, leading and management of research groups as well as some experience in university administration is desirable. Letters of application, a curriculum vitae and a list of publications should be addressed before June 30 1989 to:

Secretariat de la Faculté des Sciences,  
20, quai Ernest-Ansermet,  
CH-1211 Geneva 4, Switzerland

where additional information may be obtained. (W5986)A

#### ASSISTANT PROFESSOR

#### QUANTITATIVE EPIDEMIOLOGY OF PLANT PATHOLOGY

Applications are invited for a tenure-track position to conduct independent and collaborative research on the quantitative epidemiology of plant pathogens. Teaching duties include development of a graduate course in quantitative epidemiology. A Ph.D. with demonstrated expertise in quantitative biological research is required. Postdoctoral experience is preferred. Send curriculum vitae, transcripts, selected reprints, a statement of research interests and three letters of reference to: Dr. A. H. Epstein, Iowa State University, Dept. of Plant Pathology, Ames, IA 50011-1020, 515-294-1741. Deadline: May 15, 1989, or until position is filled.

Affirmative Action/Equal Opportunity Employer. (NW3497)A

#### Position announcement

GEOMAR, Research Center for Marine Geosciences which was established in 1987 at the Christian-Albrechts-Universität in Kiel/Germany, invites applications for a C-1 appointment in

#### Marine Environmental Geology

C-1 is the classification in the German civil service system equivalent to Assistant Professor.

The successful candidate will be expected to develop a research program on natural recycling processes at the seafloor as well as participate in the build-up of the Research Center. Desired expertise in one or more of the specialties: trace elements, biomarkers, organic-mineral interaction.

Ph.D. or equivalent degree is required. Women are encouraged to apply. Please send applications, including resumé and addresses of three references, before May 15, 1989 to:

GEOMAR  
Research Center for Marine Geosciences  
Personnel Department  
Wischhofstrasse 1-3  
D-2300 Kiel 14  
Fed. Rep. Germany

(W5988)A

#### MOLECULAR VIROLOGY FULL PROFESSOR (C4) UNIVERSITY OF MÜNSTER FR – Germany

The University of Münster is establishing a clinical research center for 'Molecular Biology of Inflammation'. It will finally comprise five new Institutes and five associated research groups. The first position (tenure track, full professorship) is now offered to an experimental molecular virologist. The successful candidate will be the director of the newly founded institute with due regard to the regulations of § 29 Wiss. HG.

Applicants should have a background in either Herpes virus or retro-virus research (e.g. AIDS). Participation in regular basic teaching in virology is expected. Applicants from abroad are encouraged.

Please send curriculum vitae, bibliography, an outline of research interests and of teaching experiences to the:

Dekan der Medizinischen Fakultät  
Domagkstraße 3  
D – 4400 Münster  
FR – Germany

Closing date: 12.06.1989

Telefon: 01049251/83 5490

Telefax: 01049251/83 6960

(W5987)A

#### Forestry Research Coordination Committee

FRCC

#### FARM FORESTRY

At least £450k will be available over 3 years for research into the environmental, economic and social aspects of farm forestry. This Special Topic Programme is being launched by the Forestry Research Coordination Committee and will be jointly funded by the Department of the Environment, the Forestry Commission and the Natural Environment Research Council. Applications for research grants and research studentships are invited from centres of Higher Education and recognised research institutes.

Further details and application forms from:  
Colin Barr, NERC, Polaris House,  
North Star Avenue, Swindon SN2 1EU.  
Closing date for applications: 28 April 1989.

(8825)A

# THE HANNAH RESEARCH INSTITUTE

## IMMUNOLOGIST/ BIOCHEMIST

An immunologist or a biochemist with experience in immunology is required to investigate the autoimmune control of milk secretion. The appointee will join a team within the Director's Research Group which is studying local mechanisms regulating mammary function. Techniques will include EPLC, polyclonal and monoclonal antibody production, and radioimmunoassay and enzyme immunoassay development. The post is funded for 2 years.

Applicants should possess a first or upper second class degree in immunology, biochemistry or a related discipline, with at least 2 year's relevant experience.

Appointment will be at Higher Scientific Officer grade, with starting salary up to £10,994. A non-contributory superannuation scheme is operating.

Further details may be obtained from The Secretary, The Hannah Research Institute, AYR KA6 5HL to whom applications, including the names of two referees should be forwarded by 8 April 1989 quoting reference HRI/165. (8801)A

# UNIVERSITY OF DURHAM DEPARTMENT OF CHEMISTRY SENIOR RESEARCH ASSISTANT IN ORGANIC CHEMISTRY

Applications are invited from organic chemists with a Ph.D. degree for work on the synthesis of novel materials containing fluorocarbon units, with potential wide applications. Work will be supervised by Professor R. D. Chambers and carried out in close collaboration with industry. Background experience in free-radical reactions or polymer chemistry would be useful but not essential. The post is tenable from March 1989 for one year but renewal for up to three years is anticipated.

Salary will be in the range £9,865-£11,070 per annum.

Applications (three copies) naming three referees should be sent to the Registrar, Science Laboratories, South Road, Durham, DH1 3LE, as soon as possible. For further information telephone Professor R. D. Chambers (tel. (091) 374-3120). (8795)A

## Develop your research skills - and career - in a pioneering Research Unit

# Scientist/Senior Technician

An impressive range of well established pharmaceuticals has won Ciba-Geigy the respect of colleagues and competitors throughout the industry. Our reputation for innovation is exemplified by our Advanced Drug Delivery Research Unit, presently working on designing means of achieving site-specific delivery of conventional and genetically defined drugs. It is in this Unit that we need a Scientist/Senior Technician in the cell biology research area.

If you're keen to work on projects of considerable challenge and potential, you'll be interested in joining us at our superbly equipped laboratories in Horsham.

We operate a flexible career structure, allowing senior technicians to move up into scientific grades. So you may be a young Graduate, with up to 2 years' experience, or an HNC/HND qualified professional with a solid background in a similar industrial or public sector environment. Either way, you'll be self-motivated, and be equally capable of working on your own or within a multi-disciplinary team. A practical 'hands on' approach is crucial.

Familiarity with cell culture, biochemical and/or immunological analytical techniques is particularly relevant, because you will be helping to determine epithelial transport pathways for macromolecules in vitro, as well as the evaluation of novel delivery systems.

Along with outstanding prospects for personal and professional development, you'll receive a competitive salary backed by a full range of major company benefits.

Please write, enclosing your full C.V. quoting reference V41 to: The Personnel Department, Ciba-Geigy Pharmaceuticals, Wimblehurst Road, Horsham, West Sussex RH12 4AB. Tel: (0403) 50101.

# CIBA-GEIGY

(8831)A

## HERIOT-WATT UNIVERSITY DEPARTMENT OF BIOLOGICAL SCIENCES LECTURER

Applications are invited for a lectureship under the New Academic Appointments Scheme designed to recruit younger academic staff.

This is not a fixed term appointment and it will be associated with the International Centre for Brewing & Distilling and the lecturer will be expected to carry out teaching and research in areas of relevance to the malting, brewing and distilling industries. Preference will be given to candidates with experience of research at a post-doctoral level in either plant or yeast molecular biology.

The salary will be on the Lecturer A scale £9,260-£14,500 (under review). Further particulars and application forms are available from the Staff Officer, Heriot-Watt University, Riccarton, Edinburgh EH14 4AS. Please quote ref no 26/89/N. Closing date 21st April. (8809)A

## CENTRAL VETERINARY INSTITUTE Lelystad, The Netherlands

### The Department of Virology seeks to recruit 2 MOLECULAR BIOLOGISTS

to work in a research group dealing with the construction of a vaccine based on a deletion mutant of bovine herpesvirus type 1, that also serves as an expression vector of genes for bovine respiratory virus.

The posts are funded for a period of 4 years.

Candidates with a Ph.D. degree in the biological sciences and a broad experience in DNA-recombinant technology are invited to apply.

Salary is within the range of Dfl. 50.000-80.000 (approx. \$23.000-36.000) per year.

For enquiries phone Dr. J.T. Van Oirschot (03200-73911, ext. 308), or Dr. A.L.J. Gielkens (03200-26814).

Application with full curriculum vitae and names of 2 referees should be submitted within 3 weeks to the Personnel Office, The Central Veterinary Institute, P.O. Box 65, 8200 AB Lelystad, The Netherlands. (W6001)A

Department of Scientific and  
Industrial Research

## SCIENTIST-EMBRYOLOGY

Biotechnology Division

(Ref no: Bio 14)

A vacancy exists in an expanding group using cell culture techniques to produce embryos for a transgenic ruminant animal programme.

A scientist is needed who has experience in vitro maturation and fertilisation of ruminant oocytes and embryo culture.

This person will be actively involved in collaborating with molecular biologists to produce transgenic animals.

Applicants should possess a Ph.D. in physiology, biochemistry, animal or veterinary science.

The applicant for this position should be able to work effectively in a multi-disciplinary group.

The position is for three years initially.

Salary will be commensurate with qualifications and experience.

Please apply in writing and enclose a Curriculum Vitae including the names of at least two referees by 14 April 1989 to:

The Personnel Officer  
DSIR, Private Bag  
Palmerston North  
New Zealand.

(W5994)A

### UNIVERSITY OF LONDON CHAIR OF GEOLOGY TENABLE AT BIRKBECK COLLEGE

The Senate invite applications for the above Chair tenable from 1 October 1989.

Applications will be considered in all branches of geology/geophysics. The successful applicant will have demonstrated high research capabilities and potential, and will be expected to set up and lead a research team in his/her own field. He/she will also contribute as appropriate to teaching on BSc and MSc courses and to departmental administration.

Applications (10 copies) should be submitted to the **Teachers' Section (N), University of London, Senate House, Malet Street, London WC1E 7HU, from whom further particulars should first be obtained.**

The closing date for receipt of applications is 28 April 1989. (8800)A

### ATMOSPHERIC PHYSICIST

to carry out field and laboratory studies related to cloud radiation and electrification processes. Duties include aircraft and cloud data reduction and analysis; design and construction of measurement systems; and program development. Requires Ph.D. in Physics or related discipline, with experience in aircraft and/or laboratory cloud physics/chemistry; working knowledge of electronics and computing related to aircraft operations and/or laboratory instrumentation. Position will be filled at either the Assistant or Associate Professor level, rank and salary dependent upon qualifications.

Applications must be received by 5/31/89.

Send resume and letter of interest to Personnel Office, Desert Research Institute, University of Nevada System, P.O. Box 60220, Reno, NV 89506.

An Affirmative Action/Equal Opportunity Employer.

(NW3502)A

ROYAL HOLLOWAY AND BEDFORD

NEW COLLEGE

University of London

School of Life Sciences

DEPARTMENT OF BIOCHEMISTRY

### TWO LECTURESHIPS IN PLANT BIOCHEMISTRY MOLECULAR BIOLOGY

Applications are invited for these two posts in the Plant Exploitation and Protection Group, in association with the appointment of Dr Bowyer to the Chair in Plant Biochemistry. The main research interests of the Group are the structure and assembly of Photosystem the biosynthesis of carotenoids and gibberellin plant growth regulators, and cell wall biochemistry.

Applicants should have a good research record in the use of recombinant DNA techniques to study either primary plant metabolism or its regulation, photosynthesis, regulation of plant development, signal perception and transduction or organelle biogenesis. The successful candidates will be expected to develop vigorous externally funded research programmes, and applications should include outline proposals for future research.

The College is situated 20 miles outside central London on a wooded campus site near Windsor, Heathrow and the M25.

The appointments, to take effect from October 1989, will be at appropriate points on the Lecturer grade A (£10,910-£16,150) or B (£16,700-£20,960) including London allowance, according to qualifications and experience.

The positions may be discussed informally with Professor J R Bowyer (telephone 0784 34455 ext. 3803). Further details may be obtained from the **Personnel Office, Royal Holloway and Bedford New College, Egham Hill, Egham, Surrey, TW20 0EX**, to whom applications (three copies) including cv, publication list and the names of three referees should be sent not later than April 30th 1989. (8796)A

### INSTITUTE OF CANCER RESEARCH Programmer/Statistician

This post is with the joint Department of Physics of the Institute of Cancer Research and the Royal Marsden Hospital, to assist with research aimed at improving the effectiveness with ultrasound as applied to cancer medicine. It is concerned with the management, processing and statistical analysis of data acquired from the ultrasound images and would be suitable for someone with a background in computer programming, statistics, a physical science, or a related subject. An interest in computer databases and/or expert systems would be useful.

The Physics Section has an active and broad-based research and teaching programme and provides a stimulating environment for someone wishing to work in the bio-medical field. The post will be based at the Sutton Surrey campus. Good sports and social facilities are on-site.

Appointments will be on MRC salary scales for technicians, in the range £7811-£10711 per annum (including London Weighting).

Informal enquiries can be made to Dr. J.C. Bamber on 01-642-6011, ext. 3343.

Applicants are advised that smoking is prohibited in the majority of the Institute's premises.

To apply, please submit a Curriculum Vitae, in duplicate, with the names and addresses of two referees to **The Personnel Officer, the Institute of Cancer Research, 17a Onslow Gardens, London SW7 3AL** quoting reference number 1.89.T.N.65. (8816)A

### UNIVERSITY OF BIRMINGHAM

Department of Social Medicine

Applications invited for the post of

### RESEARCH ASSOCIATE 1B

to work on an MRC funded project examining the effects of smoking and stopping smoking in pregnancy on the long-term physical and cognitive development of the child. Applicants should have a degree in either single or joint honours psychology and should have used a car. Suitable applicants could register for the degree of PhD.

The appointment is for a three year period from July, August or September 1989. Salary on scale £8,675-£11,680 plus superannuation.

Further particulars and application form available from **Senior Assistant Registrar, Medical School, Birmingham, B15 2TJ** to whom **completed applications (3 copies) should be sent by 17th April 1989**. Quote Ref: RA/SM/CMC.

AN EQUAL OPPORTUNITIES EMPLOYER (8789)A

# MOLECULAR BIOLOGISTS

## DEVELOP THE BIOPHARMACEUTICAL PRODUCTS OF THE 1990s

Celltech is one of Europe's foremost biotechnology companies. From our purpose-built facilities in Slough, we are among the leaders in the research and manufacture of protein-based drug products – the therapeutics for the 1990s and beyond.

We now have a number of opportunities for experienced molecular biologists to join our existing teams in the successful Research Division.

A **Senior Research Scientist** to join our Eukaryotic Molecular Biology Group working on gene expression and heterologous protein secretion. The ideal candidate will be primarily responsible for carrying out innovative research into yeast and mammalian recombinant host systems.

With a PhD in Molecular Biology/Genetics, you will have had up to 3 years' post-doctoral experience of independent research in academia or industry. Ideally, you should have a knowledge of yeast/fungal genetics and also an interest in prokaryotic and mammalian expression. **Ref: 199.**

A **Senior Research Scientist** to join our Mammalian Expression Group working on the expression of recombinant products from mammalian cell lines and making a significant contribution to the development of new products.

Qualified to PhD level, you should have up to 3 years' post-doctoral research experience in Molecular Biology/Molecular Genetics, preferably of eukaryotic cellular functions. You will also have proven ability in conducting independent research and a keen interest

in applying your knowledge as part of a strong team developing novel methods of gene expression. **Ref: 228.**

A **Life Scientist** to join our Eukaryotic Molecular Biology Group engaged in innovative recombinant technology and tissue culture research. You will work on the cloning and expression of recombinant protein in mammalian and microbial host systems, and help to develop our portfolio of biopharmaceutical products.

You should have a good honours degree in a Biological Science, with emphasis on molecular and cell biology. With up to 3 years' academic or industrial laboratory experience, you will have developed a knowledge of animal cell culture and preferably recombinant DNA technology. **Ref: 262.**

Celltech is a young company: attracting and retaining the very best people has been vital to our success, and will always be a key priority. Whether working on your own initiative or as part of a multi-disciplinary team, you'll find that good interpersonal skills are essential in our fast-moving and results-oriented environment.

You can be sure your potential will be recognised and valued – our scientists enjoy competitive salaries and excellent career opportunities, supported by a comprehensive benefits package and relocation assistance where appropriate.

Please write with full details of your experience to date and quoting the relevant reference number to Mrs Jane Smith, BSc C BIOL MI BIOL, at Celltech, 216 Bath Road, Slough, Berkshire SL1 4EN.

## ENDOCRINOLOGY DIVISION

### Cell Biologist

We seek a post-doctoral scientist to develop cellular aspects of endocrinology applied to the characterization and standardization of hormones, including those derived from modern biotechnologies, and associated research work. The appointment will be initially for five years with the possibility of tenure at the end of that period.

The Successful Candidate will be expected to establish endocrine cell lines and study the actions of hormones, growth factors and other protein modulators. Experience in cell culture and molecular aspects of peptide hormones will be an advantage.

The Institute is located in newly-built premises in Hertfordshire, within reach of St Albans and central London and offers excellent facilities for modern biological and molecular sciences.

Salary will be on Medical Research Council scales, dependant on age, qualifications and experience.

*Informal enquiries may be made to Dr S L Jeffcoate, ext 227.*

To apply please submit a full C.V. together with the names and addresses of three referees to: **The Personnel Office, National Institute for Biological Standards and Control, Blanche Lane, South Mimms, Potters Bar, Herts EN6 3GQ.** Telephone 0707 54753 Ext 458. Please quote reference HO/047A.

**Closing date for applications: 14th April 1989.**

**NIBSC**

National Institute for Biological Standards and Control  
(8811)A

## Pharmacology of Shock & Inflammation

### Merck Sharp & Dohme Research Laboratories

MSDRL is recognized as the number one pharmaceutical company in the world, with an outstanding reputation for basic research and its application to the discovery and development of safe and effective medicines.

The Department of Cellular and Molecular Pharmacology of Merck Sharp & Dohme Research Laboratories is engaged in multi-disciplinary studies aimed at developing novel therapeutic strategies for the treatment of inflammatory diseases. As part of our expanding research program, we seek an experienced Ph.D. Scientist with broad-based expertise in the measurement of cardiovascular and/or pulmonary function in animal (dogs, swine, sheep, non-human primates) models of shock and inflammation.

Qualified candidates will be creative and enthusiastic scientists with relevant post-doctoral research experience, a sound publication record and excellent communication skills.

Merck Sharp & Dohme Research Laboratories are located in Rahway, New Jersey approximately 25 miles from New York City. Our salaries, benefits and growth potential are excellent. Interested candidates should submit their curriculum vitae with the names of three references and salary requirements to: **Ms. Lonnie L. Deetz, R80M-TL1, Merck & Co., Inc., P.O. Box 2000, Rahway, NJ 07065.**

AN EQUAL OPPORTUNITY EMPLOYER

(NW3506)A

**Merck & Co., Inc.**

## THE UNIVERSITY OF ZAMBIA

Applications are invited from suitably qualified candidates to fill the following posts:

### SCHOOL OF MEDICINE

#### DEPARTMENT OF ANATOMY

#### Associate Professor/Senior Lecturer/Lecturer (3 posts)

Applicants should have a higher degree (M.Sc., Ph.D or equivalent) in morphological Science. A medical degree (M.B., Ch.B., M.D. or equivalent) is desirable but not essential for applicants with experience in teaching and research in human anatomy in a Medical or Dental School. Duties will involve teaching medical undergraduate and postgraduate students and various cadres of paramedicals (post-basic nursing, physiotherapy etc.). The human anatomy course is divided into four subcourses: Gross Anatomy, Histology, Embryology and Neuroanatomy, and the successful applicant will be required to teach at least two of these fields.

### SCHOOL OF NATURAL SCIENCES

#### DEPARTMENT OF BIOLOGY

#### Senior Lecturers/Lecturers in the following areas:

Molecular Biologists with interest in Cell Ultrastructure, Protein Structure and Function, Biomembranes and Bioenergetics.

Animal Physiologist with interest in reproductive biology.

Entomologist with interest in vector biology of parasites.

Geneticist specialising in cytogenetics with interest in population genetics.

Tracheophyte Biologist able to teach taxonomy, morphology and anatomy of angiosperms and gymnosperms.

Applicants are required to lecture to second up to fourth year students and should have a Ph.D with 2-3 years post-doctoral research experience, preferably University level teaching and a demonstrated interest in research.

### SCHOOL OF AGRICULTURAL SCIENCES

#### Professor/Senior Lecturer/Lecturer in Farm Management

Applicants should have an M.Sc or Ph.D degree in Agricultural Economics with emphasis on Farm Management. Extensive teaching and research experience at University level in a developing country preferred. Duties will include conducting lectures and tutorials in Production Economics, Farm Accounts, Farm Budgeting and Planning, and Farming Systems to undergraduate students; supervising practical training of students; initiating research or continuing on-going research into management problems of Peasant and Commercial farms in Zambia.

#### Professor/Senior Lecturer/Lecturer in Extension Education/Rural Sociology

Candidates should have an M.Sc or Ph.D degree in Agricultural Extension Education/Rural Sociology with extensive teaching experience at the University level. Research and extensive experience in Africa/developing countries would be preferred. The appointee will teach and conduct tutorials in Agricultural Extension/Rural Sociology undergraduate courses; supervise practical training of students; and carry out socio-economic research related to the needs of Zambia.

Salaries: Entry point and salary will depend on qualifications and experience in the range of (per annum): Professor ZMK 50,652-55,260; Associate Professor ZMK 42,600-48,648; Senior Lecturer ZMK 36,204-44,844; Lecturer Grade I ZMK 32,604-37,836; Lecturer Grade II ZMK 27,252-31,860; Lecturer Grade III ZMK 24,348-26,364.

All posts are tenable immediately and the University offers contracts of up to four years (renewable). Other benefits include family passages; annual leave; children's education allowance and holiday passages; non-practising allowance for medical personnel etc.

Detailed applications with full curriculum vitae, and three names and addresses of referees should reach the Registrar, University of Zambia, P.O. Box 32379, Lusaka, Zambia, not later than 10 April 1989. (W5996)A

in science — EVERY WEEK

## UCLA CELL AND MOLECULAR PHYSIOLOGY

The Department of Physiology invites applications for tenure track faculty positions at the level of

# Assistant Professor

Outstanding candidates working in any area of contemporary physiology will be considered, but those in smooth muscle, reproduction and development, endocrinology, sensory transduction, and the cardiovascular system are encouraged to apply. Successful candidates are expected to have a Ph.D. or M.D. with post-doctoral experience, to provide evidence that they can pursue a vigorous, independent research program and to participate in our teaching program.

Resources and an excellent environment exists for developing an academic career within an interactive community. Interested scientists should send their curriculum vitae, a statement of present and future research interest, and names of three references to:

**Ernest M. Wright, D.Sc.,  
Professor and Chairman,  
Department of Physiology,  
UCLA School of Medicine,  
Los Angeles, CA 90024-1751.**

The University of California is an Equal Opportunity Affirmative Action Employer.

(NW3500)A

### UNIVERSITY OF BRISTOL DEPARTMENT OF PHYSIOLOGY POSTDOCTORAL RESEARCH FELLOW IN SENSORY NEUROPHYSIOLOGY

Applications are invited for a three-year M.R.C.-funded post, starting on July 1st or as soon as possible thereafter, to study the immunocytochemical and electrophysiological properties as well as the ion channels of primary sensory neurones with known sensory receptor properties. Intracellular recordings will be made in an *in vitro* skin/nerve/ganglion preparation. Experience in electrophysiology an advantage. Salary on Grade 1A scale.

Informal enquiries can be made by telephoning Dr Sally Lawson on 0272 303463.

**For further details telephone Bristol 303136 (ansaphone after 5.00 p.m.) or write to the Personnel Office, Senate House, Bristol BS8 1TH. Please quote reference A287.**

*An Equal Opportunities Employer* (8790)A

### PROFESSORSHIP OF MICROBIOLOGY

Applications are invited for the above vacant office in the Department of Food Microbiology.

Salary scale: IRE30,747-IRE35,567 p.a.

Application forms and further details may be obtained from the undersigned. Latest date for receipt of completed applications is **Friday, 28 April, 1989.**

M.F. Kelleher  
Secretary

(8828)A

Coláiste na hOllscoile Corcaigh  
University College Cork

### JOHN INNES INSTITUTE **Seeds**

## POSTDOCTORAL RESEARCH APPOINTMENT IN MOLECULAR PLANT VIROLOGY

Applications are invited for a postdoctoral research scientist for a project funded by ICI Seeds in the Department of Virus Research of the John Innes Institute. The project concerns the isolation and molecular characterization of sugar beet viruses. Experience in molecular biology is desirable, but not essential. The successful applicant will join an active research group working on various aspects of plant virus molecular biology. The appointment will be for two years duration. Further particulars may be obtained from Dr R Hull at the John Innes Institute.

The appointment will be on the University R & A 1A scale and the salary in the range £9,865 to £15,720. Contributory superannuation scheme. Equal Opportunities Employer.

Applications with full particulars, CV, and the names of two referees should be sent to the **Personnel Officer, John Innes Institute, Colney Lane, Norwich, NR4 7UH** to arrive not later than 24 April 1989. Quote reference VIR/348.

*The John Innes Institute is associated with the AFRC  
Institute of Plant Science Research.* (8822)A

## MERRELL DOW RESEARCH INSTITUTE STRASBOURG CENTER

### Postdoctoral behavioural pharmacologist

We have an opening for a postdoctoral (Ph.D) behavioural scientist to establish animal models of learning and memory as part of a program aimed at the development of novel remedies for cognitive disorders. Prior experience of testing cognitive function in animals is essential for this post. The position is available for a period of 1-2 years. The Merrell Dow Research Institute has a liberal publication policy. Knowledge of French is desirable, but not a requirement for this position. Interested applicants should send a curriculum vitae and names of three references to:

Mrs M.J. BILDSTEIN, Personnel Manager Merrell Dow Research Institute, 16 rue d'Ankara,  
F-67084 STRASBOURG Cedex.

(W5984)A

## UNIVERSITY OF DUNDEE DEPARTMENT OF BIOLOGICAL SCIENCES POST-DOCTORAL RESEARCH ASSISTANT

Applications are invited to fill the above AFRC-supported position to work with Professor John Raven and Dr Janet Sprent on the role of soil-nodule exchanges in the iron, molybdenum, acid-base and water economy of  $N_2$ -fixing legumes.

Salary on the Research Assistant 1A scale (£9,865-£15,720). Initial salary (age 27+) will be at £11,680.

The position is available for three years from 1 May 1989 or as soon thereafter as can be arranged.

Applications in writing, including a full CV (2 copies) and the names of two referees, as soon as possible to, the **Personnel Office, The University, Dundee, DD1 4HN**. Please quote ref: EST/410/89/N.

Informal enquiries to Professor Raven, University of Dundee, Tel. (0382) 23181 Ext. 4281, from whom further particulars can be obtained. (8805)A

MEDIA SYSTEM

KAROLINSKA  
INSTITUTE  
STOCKHOLM,  
SWEDEN  
DEPARTMENT OF  
CLINICAL GENETICS

### Postdoctoral research assistant in molecular genetics

Applications are invited from PhD graduates with a background in molecular genetics for a postdoctoral research position on any of the following projects for a minimum of 12 months:

1. Molecular endocrinology; gene structure and function in Non-Insulin-Dependent-Diabetes, 21-Hydroxylase Deficiency, and of the human growth hormone independent binding protein for insulin-like growth factors
2. Genetic toxicology; molecular mechanisms of spontaneous and induced mutations in human somatic cells
3. Cancer genetics; molecular and chromosomal mechanisms of human cancer and inherited predisposition to neoplasia

Applications including Curriculum Vitae and names and addresses of two referees should be sent to:

**Professor Jan Lindsten,**  
Department of Clinical Genetics,  
Karolinska Hospital,  
S-10401 Stockholm, Sweden.

tel +46-8-729 2469; fax +46-8-32 77 34

(W6002)A

## RESEARCH SCIENTIST MOLECULAR BIOLOGIST: MOLECULAR GENETICIST

A six-year tenure track position is available in the ICRF Laboratory of Molecular Pharmacology in Edinburgh. The overall aims of the group are to understand the factors which determine individual susceptibility to cancer as well as molecular mechanisms of tumour cell resistance to cytotoxic drugs. Candidates should have a strong background in eukaryotic or prokaryotic molecular biology and/or molecular genetics and will be expected to work independently on themes complementary to the main aims of the group.

The ICRF group is situated in the University of Edinburgh Department of Biochemistry and works closely together with other Departments in the University. The successful candidate will be considered for an honorary position within the University.

Salary range: £14,500-£23,000

For further information contact Dr. C. R. Wolf, I.C.R.F. Lab of Molecular Pharmacology, Hugh Robson Building, George Sq., Edinburgh EH8 9XD, U.K. Tel: 031-668-3343.

**Applications should be made by sending a full curriculum vitae together with the names and addresses of three referees to the Recruitment Officer, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX quoting reference 78/R.**

Closing date for applications: 21st April 1989

Smoking is actively discouraged.

(8834)A

**I M P E R I A L  
CANCER RESEARCH FUND**

## UNIVERSITY OF ST ANDREWS DEPARTMENT OF PSYCHOLOGY

Applications are invited for the post of

### RESEARCH TECHNICIAN GRADE 5

required for international joint research prospect on "Temporal lobe mechanism in Memory" supported by Japanese NEDO. The project will focus on visual neurones responsive to meaningful stimuli (faces and actions).

The post is available from April 1st for one year in the first instance (renewable for two years) at a starting salary of £8,088 per annum. Applicants should have HNC or equivalent, together with experience in either biological science or electronics/computing.

The appointee will be involved in electrophysiological data collection. Enquiries and applications with a full curriculum vitae and names of two referees familiar with the applicants work should be sent to **Dr D Perrett, Psychology Department, University of St Andrews, St Andrews, fife, KY16 9JU** as soon as possible. (8808)A

## MATHEMATICAL GEOLOGIST

The sandstone cementation, cation transport, heat and fluid movement in the 360 Myr old sedimentary basin of N. England is being researched by three Ph.D students. A central part of the project is to quantify mass transfer of minerals, heat and oil by **developing computer models** of ancient compactional fluid flow or diffusion through subsiding porous rock in this basin and the North Sea. We need a strong mathematical or computing background with a Ph.D, or a BSc. plus relevant experience in porous media fluid flows. Based at Glasgow University, with excellent VAX and SUN computing in Dept. Salary 3yrs on 1A scale starting £11,015. Apply with CV and three referees by 4 weeks after publication date to **Dr. R S Haszeldine, Applied Geology, Glasgow G1 1XJ, Scotland. Tel 041-552-4400 ext 2148.** (8823)A

**SOUTHAMPTON GENERAL  
HOSPITAL**

WESSEX REGIONAL  
IMMUNOLOGY SERVICE

**SENIOR SCIENTIFIC  
OFFICER**

To take charge of monoclonal antibody production, standardisation and use for immunophenotyping of patients with haematological neoplasms and immunodeficiency disorders. Research activities and industrial liaison encouraged. Post would suit recent Ph.D.

Salary: £11,778-£15,394.

For informal visits contact Dr. J.L. Smith on (0703) 777222 Ext. 3490.

Application form and job description from Unit Personnel, Level C, Centre Block, Southampton General Hospital, Southampton, SO9 4XY. Tel. (0703) 777222 Ext. 4100.

Closing date: 6.4.89.

Working Towards Equal Opportunities. (8806)A

**UNIVERSITY OF  
MANCHESTER  
DEPARTMENT OF CHEMISTRY  
POST-DOCTORAL RESEARCH  
ASSOCIATE IN ORGANIC  
SYNTHESIS**

Applications are invited for this SERC funded post to work with Professor E. J. Thomas on the total synthesis of a group of biologically active marine natural products. Initial salary range £9,865 - £11,680 p.a. Superannuation.

Appointment will be for one year in the first instance, starting on October 1st, 1989.

Applications including a c.v. and the names and addresses of two referees should be sent as quickly as possible to **Professor E. J. Thomas, Department of Chemistry, the University, Manchester M13 9PT** from whom further particulars may be obtained.

*The University is an equal opportunities employer.* (8793)A

**MOLECULAR BIOLOGIST**

Two Postdoctoral Positions — Nucleic acids experience required. (1) Work with gene transfer, regulated expression, *cis* and *trans*-acting factors regulating genes for steroidogenic enzymes. (2) Work with bacterial and yeast expression systems, maximizing expression, purifying and characterizing expressed products.

Send CV and letters of reference to **Dr. Walter L. Miller, Laboratory of Molecular Biology, Room 677-S, University of California, San Francisco 94143-0434.** (NW3498)A

**COLLEGE OF SCIENCE  
KUWAIT UNIVERSITY  
STATE OF KUWAIT**

The Kuwait University College of Science, Dept. of Botany and Microbiology invites applications for posts of Professor, Associate Professor and Assistant Professor for the academic year 1989/1990, tenable February 10, 1990 in the following disciplines:

**Plant Breeding  
Microbial Physiology  
Agriculture & Economic Botany**

The language of instruction of the College of Science is English. The method of teaching is based on the credit hour system. Applicants must hold the Ph.D. or its equivalent at the time of application. For applications and conditions of service write to:

**Kuwait University Office  
3500 International Dr., N.W.  
Washington, D.C. 20008  
(202-363-8055)**

All applications, together with non-returnable copies of academic qualifications and representative publications should be sent by registered post directly to:

**Dean  
College of Science  
P.O. Box 5969  
13060 Safat  
Kuwait**

All applications must be received by August 31, 1989.

(NW3510)A

**The Elmer V. McCollum Professor  
and  
Chair  
Department of Biochemistry  
The Johns Hopkins University  
School of Hygiene and Public Health**

Applications and nominations are invited for the position of Chairperson of the Department of Biochemistry at the Johns Hopkins School of Hygiene and Public Health. The general research interests of the current faculty include: Biochemistry — enzyme structure and mechanisms; peptide chemistry; chromatin and nucleic acid chemistry; mechanisms of nucleic acid replication, recombination and repair; structure and function of cell surface molecules; somatic mutation and antibody diversity; cell metabolism; influence of nutrition in carcinogenesis. Biophysics — structure and interaction of biopolymers in cells; synthesis of oligo- and polynucleotides of designed structure and sequence; structure and function of the mammalian genetic apparatus; development of antiviral and chemotherapeutic agents; basic mechanisms of aging. The Department also participates in a University-wide concerted effort in areas of macromolecular assemblies and interactions for which it has received considerable Federal and private support.

Candidates must have an outstanding record of research achievement in any area of biochemistry, biophysics or molecular biology, whether or not the area is currently represented in the Department; and the desire and ability to provide strong leadership to an already excellent, vibrant, growing department in the interdisciplinary setting of the School of Hygiene and Public Health.

Interested persons are encouraged to submit a curriculum vitae to:

**Dr. Barry Zirkin  
Chairman of the Biochemistry Search Committee  
Division of Reproductive Biology  
The Johns Hopkins School of Hygiene and Public Health  
615 North Wolfe Street  
Baltimore, MD 21205**

The Johns Hopkins University is an Equal Opportunity employer

(NW3504)A

## AGRICULTURAL AND FOOD RESEARCH COUNCIL (AFRC)

# HEAD OF POLICY, PLANNING AND ASSESSMENT

Swindon

up to £36,700

The AFRC undertakes basic and strategic research underpinning the agricultural, food and emerging biotechnological industries of the UK. Research is carried out in institutes, universities and other HEIs. The AFRC has 4,700 staff and an annual budget of £135m.

The Head of Policy, Planning and Assessment will lead a team helping to shape future development of the Council's scientific activities. These relate, for example, to environmental issues, novel applications of genetic expression in plants and animals, food quality and safety; and the implications for British research of the single European market. The person appointed will have a central role in the Council's planning activities, including responsibility for the annual AFRC Corporate Plan. The post also carries responsibility for developing procedures for the Council's management of research, including monitoring and assessment through performance indicators and the development of management information systems. Policy analysis and briefing for the Secretary

of the Council are an important continuous activity.

Candidates should have a background in scientific research, preferably in the biological sciences, and an understanding of the administrative machinery of government and the Research Councils. Experience in quantitative analysis and in economic assessment would be an advantage. Strong qualities of oral and written communication are essential.

Starting salary will be on a scale between £28,170 and £31,602. Performance-related increments are attainable, with further increases to £36,786. Benefits are similar to those in the Civil Service.

Please apply in writing for an application form to: Mr R J Davies, Manager, Central Office, Agricultural and Food Research Council, Wiltshire Court, Farnsby Street, Swindon, Wilts SN1 5AT.

Closing date for receipt of completed application forms: 14th April 1989.

The AFRC is an equal opportunities employer.

(8832)A

## UNIVERSITY OF OXFORD NUFFIELD DEPARTMENT OF PATHOLOGY AND BACTERIOLOGY

John Radcliffe Hospital  
Headington OXFORD OX3 9DU

### Postdoctoral Research Assistant

Applications are invited for a postdoctoral position to work on gene abnormalities and transcription in human breast cancer. The person appointed should have experience in molecular biology. The successful applicant will work in the relatively new group of about 10 people who are investigating the molecular pathology of "early" human breast cancer.

The salary is funded by the Cancer Research Campaign for 3 years in the range of £8,675 - £13,365.

Applications, with the names of referees, should be sent to Professor J. O'D McGhee at the above address by 13.4.89. He will provide detailed particulars of the specific problem being investigated by this Group.

Oxford University is an equal opportunity employer. (8820)A

## The Faculty of Medicine, University of Geneva has an opening for a

### FULL PROFESSOR IN ITS DEPARTMENT OF PATHOLOGY

This is a full time post. The successful candidate will be the Chairman of the Department of Pathology and Chief of the Institute of Hospital Pathology; the post involves the responsibility for teaching at the pre- and post-graduate level; supervision of seminars and of clinical research.

Qualification required: M.D.

Board qualified (or equivalent)

Stating date: 1st of October 1989 or by arrangement.

Applications and CV should be sent until 30 May to the

**Secrétariat de la Faculté de Médecine**

**Centre Médical Universitaire**

**1 rue Michel-Servet, 1211 Genève 4, Switzerland**

**Phone 022/22.91.82**

where further particulars of the post can be obtained.

(W5990)A

### TENURE-TRACK POSITION

available for Ph.D. or M.D. at assistant or associate professor rank to evaluate cell-mediated immune responses to HIV infections and vaccines. Candidates will be expected to develop vigorous research program, with opportunity to participate in evaluations of other viral and parasitic vaccines under investigation at the Center for Immunization Research.

Primary appointment is in the Department of Immunology and Infectious Diseases in School of Public Health; option for joint appointment in Division of Infectious Diseases in School of Medicine.

Please submit C.V. and names of 3 references to

**Dr. Noel Rose c/o Dr. M.L. Clements,**

**Johns Hopkins University**

**(JHU) Center for Immunization Research,**

**624 North Broadway, Baltimore, MD 21205.**

JHU is an Equal Opportunity/Affirmative Action Employer.

(NW3496)A

## AMERICAN ASSOCIATION FOR CLINICAL CHEMISTRY, INC.

### EDITOR OF CLINICAL CHEMISTRY

The American Association for Clinical Chemistry, Inc., invites nominations for position of Editor of *Clinical Chemistry*, the world's leading journal in clinical laboratory science with a circulation of 15,000 and one of the 100 journals most frequently cited.

Candidates must hold the Ph.D. or M.D. degree and have broad knowledge of clinical chemistry and extensive experience in scientific and medical writing. The candidate should be familiar with experimental design and be able to judge the scientific validity and importance of research reports and review articles. The successful candidate will have a strong scientific record and the desire to expand and extend the scope of clinical chemistry. The candidates will have the decision making skills associated with publishing and the ability to interact constructively with the scientific community.

Both full and part-time candidates will be considered. Interested individuals should send a letter of application, a curriculum vitae, reprints of two of their publications and the names of five individuals who could serve as references by June 15, 1989, to:

**Theodore Peters, Jr., Ph.D., Chairman,  
Search Committee for Editor, Clinical Chemistry,  
American Association for Clinical Chemistry, Inc.,  
2029 K Street, N.W., Seventh Floor,

# PROTEIN CHEMIST

Hoffmann-La Roche has a unique opportunity for a **Senior Scientist** in protein chemistry to join our Molecular Structure Group and perform research leading to new pharmaceutical agents based on the three-dimensional structures of proteins as targets or templates.

You will establish and lead a protein chemistry laboratory which will purify proteins for structural determinations via crystallography and NMR spectroscopy; perform functional and mechanistic studies on the proteins; and collaborate in drug design based on this structural and functional information. Proteins to be investigated include enzymes, effectors and receptors (for example, HIV proteins).

Qualifications include a PhD in Chemistry or Biochemistry, and experience in purifying proteins using modern chromatographic methods. A strong interest in the three-dimensional structure of proteins, post-doctoral experience and knowledge of enzymology, genetic engineering, and protein expression are highly desirable.

We offer a comprehensive compensation package, and a state-of-the-art scientific environment that encourages innovation and professional growth. For consideration, please send your resume, indicating present salary, to: **Eleanor M. Malone, Department VM, Hoffmann-La Roche Inc., Nutley, New Jersey 07110.** We are an equal opportunity employer.

**Hoffmann-La Roche**

Working Today For A Healthier Tomorrow. (NW3503)A

## POST-DOCTORAL POSITION MOLECULAR IMMUNOLOGY MT. SINAI SCHOOL OF MEDICINE

A position is available to study molecular mechanisms regulating MHC gene expression following T cell activation. The relationship between MHC antigen expression and T cell function will also be studied. Training in molecular biology is desirable. Prior exposure to cellular immunology/immunogenetics would be an asset, but the position is also appropriate for someone desiring experience in these areas.

Send curriculum vitae and the names and addresses of three references to:

**Karen S. Zier, Ph.D.**  
**Mt. Sinai School of Medicine**  
**Division of Molecular Medicine**  
**Box 1055**  
**One Gustave L. Levy Place**  
**New York, NY 10029**

(NW3494)A

## NATIONAL INSTITUTE FOR MEDICAL RESEARCH GENES AND CELLULAR CONTROLS GROUP

### SHORT-TERM SCIENTIFIC STAFF POSITIONS

Applications are invited for two three year appointments to the Scientific Staff, tenable in the Laboratory of Eukaryotic Molecular Genetics (Head: Dr P W J Rigby). The research, which will be under the supervision of Dr A I Magee and Dr R S Buxton, will involve studies of the molecular biology of cell adhesion molecules associated with an intercellular junction, the desmosome. One project, that supervised by Dr Magee, (Job reference 5425/GEKG) will involve protein purification and sequencing, cell culture and the expression of cloned genes, with a view to understanding protein function. The other, to be supervised by Dr Buxton (Job reference 5311/GEKG) will involve the use of a wide range of recombinant DNA techniques to study the structure and function of cloned genes encoding desmosomal proteins. Experience in relevant techniques would be advantageous but is not essential as full training can be given in all of them.

Job reference 5311/GEKG is available immediately, the other from October 1989.

Salary is in the range £11,070-£14,500 + £1,650 London Allowance per annum.

Informal enquiries may be made by telephoning Dr Magee or Dr Buxton on 01-959 3666 extension 2224 or 2225 respectively.

Applications, including a curriculum vitae, and names of two professional referees, should be sent to **Mr C R Russell, Administrative Manager, NIMR, The Ridgeway, Mill Hill, London, NW7 1AA** quoting the relevant job reference. Closing date for this post will be 21st April 1989.

An Equal Opportunities Employer. (8818)A

**MRC**

## UNIVERSITY OF ULM

Applications are invited for the position of an

### university assistant

at the Department for Virology. The position is available for approx. 5 years.

The candidate is expected to head a small research group and has the chance to cooperate in the Sonderforschungsbereich 322 "Lymphohemopoiesis". There is a possibility for habilitation. His/her research should center around molecular problems of viral gene regulation, cell tropism or antiviral

immunity.

Applications incl. CV, list of publications, research proposal and two letters of reference by April 30, 1989, at the latest, should be directed to

**Prof. U. Koszinowski**  
**Department of Virology**  
**University of Ulm**  
**Albert-Einstein-Allee 11**  
**7900 Ulm**  
**West Germany**

(W5989)A

**ROYAL HOLLOWAY AND BEDFORD  
NEW COLLEGE**  
University of London

**DEPARTMENT OF GEOLOGY  
RESEARCH STUDENTSHIP  
IN STABLE ISOTOPE GEOCHEMISTRY**

A 3 year studentship, supported by V G Isogas Ltd, is available for research into the stable isotope geochemistry of fluid processes in the mantle and lower crust. Fluid inclusion geochemistry will be investigated using state-of-the-art gas extraction and mass spectrometric techniques.

The student will be based in the new stable isotope laboratory at RHBNC and will also have opportunities to utilise research and developmental facilities at V G Isogas Ltd. Attendance at international conferences will be encouraged.

The project will be jointly supervised by Dr D P Matthey (RHBNC) and Dr R A Exley (V G Isogas).

Applications, including a brief CV and names of two referees, should be sent to: **Dr D P Matthey, Department of Geology, RHBNC, University of London, Egham Hill, Egham, Surrey, TW20 0EX.** To obtain further information please telephone Egham (0784) 34455 ext. 3587. (8798)A

**BRITISH MEDICAL JOURNAL  
ASSISTANT EDITOR**

The BMJ seeks a new assistant editor with at least five years' experience of medical or scientific publishing. The applicant need not be medically qualified, although a qualification would be welcomed. The successful applicant will join the editorial team and will participate in selecting scientific articles and commissioning and writing articles. A broad understanding of medico-politics will be welcome as will experience of management. The journal's three senior editors are all retiring within the next two years, so opportunities for greater responsibility may arise.

**The salary will be not less than £24,000** and the starting date will be negotiable.

Applicants should send full particulars of qualifications and experience, together with the names and addresses of three people to whom reference may be made, to

**The Editor BMJ  
BMA House, Tavistock Square,  
London WC1H 9JP**  
not later than 21 April. (8819)A

**FELLOWSHIPS**

**COLUMBIA UNIVERSITY  
POSTDOCTORAL FELLOW IN  
MOLECULAR ENDOCRINOLOGY**

An NIH-funded position in the Department of Biochemistry and Molecular Biophysics is available July '89 for studies of intracellular pathways of insulin, growth factor, and proto-oncogene actions in fibroblasts. The projects use both protein biochemistry and molecular biology approaches. Experience in the biochemistry of polypeptide hormone response pathways or in molecular biology techniques desirable. US citizenship or residency required. May participate in Endocrinology and Metabolism Clinical Fellowship if an M.D. and qualified. Send curriculum vitae and names/phone numbers of three references to Dr. R.W. Rees-Jones, Department of Medicine, Columbia University, 630 W. 168th St., NY, NY 10032. *Columbia University takes Affirmative Action to ensure Equal Opportunity.* (NW3508)E

**California Institute of Technology  
The Texaco Postdoctorate Fellowship**

The California Institute of Technology announces a fellowship award from a fund endowed by the TEXACO PHILANTHROPIC FOUNDATION. This fellowship carries an annual stipend of \$32,000 from Fall 1989. Travel costs to Caltech will be covered by a supplement of up to \$1,000. The duration of the appointment will normally be one-two years.

This fellowship program has been established to support the research of scientists, typically within two years of receipt of the Ph.D. It is the intent of this program to identify and support innovative and creative work in the earth sciences, with particular emphasis on interdisciplinary work. Applicants with training in physics, chemistry, biology or computer sciences are urged to apply. The Caltech faculty is currently active in Atmospheric and Planetary Sciences, Geochemistry, Petrology, Geology and Geophysics.

Application forms may be obtained from writing to  
**Professor G. J. Wasserburg, Chairman,  
Division of Geological and Planetary Sciences,  
Mail Code 170-25 (TPF),  
California Institute of Technology,  
Pasadena, California 91125.**

**COMPLETED APPLICATIONS WITH REFERENCES  
SHOULD ARRIVE AT CALTECH BEFORE 31 MAY, 1989.**

Fellowship candidates will automatically be considered for other available postdoctoral positions at Caltech in their fields of interest.

Caltech is an Affirmative Action/Equal Opportunity Employer. Women and minorities are encouraged to apply.

(NW3499)E

**Postdoctoral  
Fellow Program**

**Biochemistry  
of Plant Lipids  
and Starches**

Applications are invited for Postdoctoral Fellowships to join a dynamic and ongoing basic research program in plant biochemistry and molecular biology. Project includes the purification and characterization of enzymes involved in starch and lipid synthesis, and the introduction and characterization of heterologous genes in oil rapeseed and potato.

Highly motivated individuals with a strong background in biochemistry and molecular biology should apply by sending a CV and the name of three references to: Calgene Fellow Program, File #782N, 1920 Fifth Street, Davis, CA 95616. An equal opportunity employer.

## MOLECULAR GENETICS/COLUMBIA UNIVERSITY POSTDOCTORAL FELLOWSHIPS

We invite inquiries from candidates with a PhD or MD degree for a two year (minimum) postdoctoral fellowship to study heritable neurological and psychiatric disorders. Two awards beginning at \$30,000 per annum are available, one immediately and one in July 1989. Preference will be given to candidates with postdoctoral experience or outstanding thesis work including chromosomal mapping and cloning, or a related area of molecular biology. Projects include mapping and cloning of disease gene regions; development of brain specific DNA markers; and computer analysis of complex banding patterns. Positions are supported by the W.M. Keck Foundation.

Please address inquiries plus curriculum vitae to: **Dr. Conrad Gillian, Molecular Genetics Laboratory, College of Physicians and Surgeons at Columbia University, Box 23, 722 West 168th St., New York, N.Y. 10032.**

EO/AA employer.

(NW3509)E

## BRITISH DIABETIC ASSOCIATION SENIOR RESEARCH FELLOWSHIP

Applications are invited from post-doctoral workers with substantial experience and achievement in diabetes research for a Senior Fellowship.

The Fellowship will provide the salary of the holder on University scales 1A or 2 and recurrent expenditure of up to £5,000 per annum. It will be tenable for 5 years in the first instance, renewable subject to satisfactory review up to a maximum of 10 years.

The closing date for applications is 8th May 1989. These should be sent to **Dr M Murphy, British Diabetic Association, 10 Queen Anne Street, London W1M 0BD.** Tel. 01-323-1531 from whom further information is available if required. (8804)E

## UNIVERSITY OF EDINBURGH DEPARTMENT OF SURGERY POST DOCTORAL RESEARCH FELLOWSHIP

Applications are invited for a post doctoral research post in the above department funded by the Cancer Research Campaign.

The project involves assessing the potential role of lymphokine activated lymphocytes in the treatment of human bladder cancer. Applicants should have previous experience of immunology and tissue culture.

The post, which is funded for 3 years, is on the 1A scale for Research and Analogous Staff, the commencing salary being up to £11,680 per annum.

Further details of the post are available from Mr A.W.S. Ritchie (031-668-3978) or Dr K. James (031-667-1011). Applications with curriculum vitae and names of 2 referees should be sent to **Dr K. James, Department of Surgery, Medical School, Teviot Place, Edinburgh.** Ref No 5653.

Closing date for applications 30th April 1989. (8830)E

## STUDENTSHIPS

## MRC PROTEIN PHOSPHORYLATION GROUP BIOCHEMISTRY DEPARTMENT, UNIVERSITY OF DUNDEE POSTDOCTORAL POSITIONS AND POSTGRADUATE STUDENTSHIPS

Following expansion of the research programme by the Medical Research Council, several postdoctoral positions have become available to work with Professor Philip Cohen and Dr Tricia Cohen. The work is interdisciplinary and applications are invited from candidates with experience in any of the following areas; molecular genetics, protein chemistry, enzymology, molecular pharmacology and immunocytochemistry. A major aspect of the research is concerned with the structure and regulation of protein phosphatases. Recent work within the Group has demonstrated that these enzymes play key roles in cell division and in tumour suppression, and several new phosphatase genes have been isolated. Novel mechanisms for controlling their activities have also been identified that involve interaction with specific targetting subunits. The positions are available from October 1989, but candidates wishing to start at any time up to Spring 1990 will be considered. The appointments are for three or five years in the first instance and will be made at an appropriate point on the University Grade 1A scale, depending on qualifications and experience. Applications are also invited for MRC and SERC postgraduate studentships, which will be supplemented in the first year by £250 (£500 for candidates obtaining a 1st class degree).

The Department is one of the most highly funded in Britain and offers outstanding research facilities and working environment. Housing and accommodation costs are among the lowest in the UK and access to outdoor recreational facilities is unrivalled.

Applications containing a full curriculum vitae and the names and addresses of three referees should be sent to **Professor Philip Cohen, FRS, FRSE, Department of Biochemistry, The University, Dundee DD1 4HN, Tayside, Scotland** as soon as possible. Informal enquiries by telephone (0382-23181) to either Philip Cohen (ext 4238, 4241) or Tricia Cohen (ext 4240). (8824)F

## Coleg Prifysgol Cymru **Aberystwyth** The University College of Wales INSTITUTE OF EARTH STUDIES

Applications are invited for College funded Research Studentships in the following fields:—

- Development of optical dating methods.
- Calcareous microfossils as geo-thermometers.
- Rare elements in fossil invertebrate skeletons.
- Pliocene global warming.
- Cretaceous anoxic events.
- Fluid movement in deforming sediments.
- Historic farming systems and the environment.
- Information technology and rural development.

It is expected that at least four awards will be made to those who have or expect to obtain good Honours degrees in appropriate disciplines. Further details may be obtained from Professor John Lewis, Institute of Earth Studies, University College of Wales, Aberystwyth, SY23 3DB. (Tel 0970 623111 Ext 3345). (8812)F

## UNIVERSITY OF ST ANDREWS DEPARTMENT OF BIOLOGY & PRECLINICAL MEDICINE RESEARCH STUDENTSHIP

Applications are invited for a 3-year SERC Earmarked Research Studentship to work with Professor I.A. Johnston at the Gatty Marine Laboratory on a project to investigate the power output and metabolic cost of muscle contraction in fish under conditions relevant to swimming. Candidates should have, or expect to obtain, a First or 2:1 honours degree in biology or physiology. Letters of application enclosing a full Curriculum vitae, which includes the names of two academic referees, should be sent to **Professor I.A. Johnston, Department of Biology & Preclinical Medicine, Gatty Marine Laboratory, University of St Andrews, St Andrews, Fife KY16 8LB, Scotland**, from whom further particulars are also available.

An Equal Opportunities Employer

## POSTGRADUATE STUDENTSHIPS

### in the FACULTY OF SCIENCE

The three Departments are Biochemistry, Genetics & Microbiology and Environmental & Evolutionary Biology. The latter includes the Marine Biological Laboratory, Port Erin, Isle of Man. Studentships will be available for research leading to a Ph.D. in the following areas:

#### Department of Biochemistry

##### Gene Structure and Function Group

1. Biosynthesis of ribosomes in animal cells with detailed analysis of rRNA methylation and pseudouridine. (Professor B. E. H. Maden)
2. Function of expression of U7 small nuclear RNA genes. (Dr. P. C. Turner)
3. Synthesis and application of 'caged' analogues of diadenosine tetraphosphate. (Dr. A. G. McLennan)
4. Identification of components of the protein translocational machinery in *E.coli*. (Dr. J. M. Pratt)

##### Molecular Oncology Group

5. Identification of putative gene(s) which upon transfection cause metastatic breast cancer in rodents. (Professor P. S. Rudland)
6. Isolation of cDNA clones for the mRNA of rat Fibroblast Growth Factor (FGF) receptor. (Dr. J. A. Smith)
7. Steroid hormone and anti-hormone regulation of specific gene expression in cultured breast epithelial cells. (Dr. C. D. Green)
8. Biochemistry and molecular biology of immune phagocytes in the role of these cells in inflammatory diseases including cancer. (Dr. S. W. Edwards)

##### Enzyme Regulation Group

9. Intracellular protein degradation in normal and pathological conditions. (Dr. R. J. Beynon)
10. The role of reversible phosphorylation in hormonal control processes. (Dr. M. J. Fisher)
11. Kinetic analysis of enzymes and the theory of pathway dynamics. (Dr. J. S. Easterby)
12. Kinetic analysis of enzymes involved in carbon fixation in chloroplasts. (Dr. R. Powls)

##### Isoprenoid Research Group

13. Hormonal control of arthropod development. (Professor H. H. Rees)
14. The regulatory role of sterol in plant cell division. (Dr. L. J. Goad)
15. Chemistry and biology of carotenoids. (Dr. G. Britton)
16. Biosynthesis and function of vitamin E in plants. (Dr. J. F. Pennock)

Contact: Dr. C. D. Green  
Tel: (051) 794 4365

#### Department of Environmental & Evolutionary Biology

1. Life history evolution in pests resistant to micropathogens. (Dr. M. E. Begon)
2. Population dynamics of damselflies. (Dr. D. J. Thompson)
3. Effects of pre-natal exposure to persistent pesticides on terrestrial mammals. (Dr. M. Stannistreet)

Further information may be obtained by writing to the named contacts at The University of Liverpool, P.O. Box 147, Liverpool L69 3BX, enclosing a curriculum vitae with the names and addresses of two referees, and indicating the research area(s) of interest.

4. Adaptive significance and physiological basis of phenotypic plasticity in grasses. (Dr. T. McNeilly)
5. Genetics of herbicide resistance in grass weed populations. (Dr. P. D. Putwain)
6. Assembly rules in arable plant communities. (Dr. A. M. Mortimer)
7. Ectocommensals and parasites as indicators of environmental change. (Dr. J. C. Chubb)
8. Interactions between periphytic algae and submerged macrophytes. (Dr. J. W. Eaton)
9. Analysis of multiple unknown organic contaminants in estuarine biota. (Dr. R. T. Leah)
10. The role of calcium in cellular control mechanisms. (Professor C. J. Duncan)
11. Cellular mechanisms of temperature and salinity adaptation. (Dr. A. R. Cossins)
12. Control of photosynthetic activity in cocoa. (Dr. K. Hardwick)
13. Role of the vacuole in salinity tolerance of marine algae. (Dr. J. C. Collins)
14. Appetite regulation in mammals. (Dr. D. M. Ensor)
15. Food value, feeding and temperature relationships in fish. (Dr. K. O'Hara)

Contact: Dr. A. M. Mortimer  
Tel: (051) 794 5127

#### Port Erin Marine Laboratory

16. Intraspecific competition in both natural and cultivated populations of seaweeds. (Professor T. A. Norton)
17. Aspects of the biology of juvenile scallops associated with cultivation. (Dr. A. R. Brand)
18. Genetic and ecological differentiation in *Actinia*. (Dr. J. P. Thorpe)
19. The ecology of the sublittoral fringe on rocky shores. (Professor T. A. Norton and Dr. J. M. Kain)
20. Micrograzing in the shallow subtidal algal undergrowth — how important? (Professor T. A. Norton)
21. Taxonomy and population genetics of *Patella* in relation to larval dispersal. (Dr. S. J. Hawkins and Dr. J. P. Thorpe)
22. Ecology and physiology of feeding in Antarctic bryozoa. (Dr. J. P. Thorpe and Dr. A. Clarke, (British Antarctic Survey))

Contact: Professor T. A. Norton  
Tel: (0624) 832027 Ext. 140

#### Department of Genetics & Microbiology

- ##### Animal Genetics
1. Molecular genetics of development in Mosquitoes. (Dr. P. Eggleston)

2. Cytogenetic studies and hypervariable DNA sequences in domestic animals/ effects of pollution. (Dr. J. J. B. Gill)
3. Molecular organization and activity of eukaryotic chromatin and chromosomes/ human cytogenetics. (Dr. R. S. Hill)

##### Fungal and Plant Physiology & Genetics

4. Control of gene expression in fungi. (Dr. M. X. Caddick)
5. Flavour synthesis in plants/fungal disease in plants. (Dr. H. A. Collin)
6. DNA repair and recombination in fungi/ genome organization in *Phytophthora*. (Dr. B. M. Faulkner)
7. Fungal disease in plants/biochemical properties of fungal protoplasts. (Dr. S. Issac)
8. Physiology and development in fungi including nutrition. (Professor D. H. Jennings)
9. Osmolyte response to environmental changes in fungi. (Dr. M. G. Jones)
10. Biochemistry and genetics of metal binding proteins and metal tolerance in plants and fungi. (Dr. D. A. Thurman)
11. Molecular genetics of metal binding proteins and metal tolerance in plants and fungi. (Dr. A. B. Tomsett)

##### Microbiology & Microbial Genetics

12. Molecular biology of thermophilic bacteria/fate of genetically-engineered-microorganisms (GEMs) in the environment. (Dr. C. Edwards)
13. Significance of antibodies to *Klebsiella* infections. (Dr. R. J. Jones and Dr. E. A. Roe)
14. Biology of *Actinomycetes* and biodegradation by bacteria/fate of GEMs in the environment. (Dr. A. J. McCarthy)
15. Biochemistry and enzyme activity of certain protozoa and bacteria/microbial decaffeination. (Dr. P. G. G. Miller)
16. Microbiology of waste water treatment and pollution. (Dr. H. W. Pearson)
17. Molecular genetics of antibiotic production in *Streptomyces* — toxic heavy resistance. (Professor D. A. Ritchie)
18. Bacterial pathogenicity and antigenic variation/fate of GEMs in the environment. (Dr. J. R. Saunders)
19. Molecular genetics of DNA repair in bacteria and fungi/toxic heavy metal resistance in bacteria. (Dr. P. Strike)
20. Biology, genetic manipulation and phenetic identification of *Streptomyces*. (Professor S. T. Williams)

Contact: Dr. R. S. Hill  
Tel: (051)-794 3628

# Sandoz Prize for Immunology

The prize will be worth US \$ 100 000 (US \$ 20 000 personal recognition/US \$ 80 000 support for research programme), and will be sponsored by SANDOZ LTD., Basle, Switzerland with the purpose of encouraging research in all areas of immunology with special emphasis on clinical immunology, including autoimmune diseases, cancer immunology, immunity to infectious diseases, transplantation immunology and discoveries in immunology leading to therapeutical applications.

Members of the Jury are G. Ada, J.-F. Bach, T. Honjo, P. Marrak, H.O. McDevitt, J.J. van Rood, R. Zinkernagel, and two representatives of Sandoz Ltd. The prize will be awarded on the occasion of an important Immunology Meeting in 1990.

Applications in English should comprise a summary of the research work of 3–5 pages, curriculum vitae, bibliography, experimental original papers separate from reviews and chapters, and reprints of not more than 3 key published papers in English or with extended summaries in English.

Individuals and research teams are invited to submit their applications not later than 30th June, 1989 to Sandoz Prize for Immunology, P.O. Box 182, 4013 Basel, Switzerland.

(W5985)N

## ASSISTANTSHIPS

### UNIVERSITY OF STRATHCLYDE DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY **RESEARCH ASSISTANT**

Applications are invited from graduates, preferably with PhD degrees in physiology and pharmacology or a related subject for a two-year industrially funded Research Assistantship to work on a project concerned with mechanisms of action of skeletal muscle relaxants used in anaesthetic practice. Experience in intracellular recording or ligand binding techniques would be an advantage. Salary: in range £8,675–£15,720 per annum.

Applications (Ref. R20/89) with full c.v. and the names and addresses of 3 referees should be sent to **Dr I G Marshall, Department of Physiology and Pharmacology, University of Strathclyde, Glasgow G1 1XQ**, who will be pleased to supply further information. Closing date for Applications:— 30 March 1989. (8803)P

### The University of Manchester **DEPARTMENT OF PSYCHIATRY** **RESEARCH ASSISTANTSHIP IN HUMAN PHARMACOLOGY**

A Research Assistantship is available in this Department for three years starting 1st October, 1989. The successful applicant will be expected to register for a PhD degree. He/she will work with a small research team on a project investigating autonomic pharmacology in healthy volunteers and patients suffering from alcoholism. The project involves both pharmacological and physiological measurements in human subjects in vivo, and biochemical assays on blood samples. Starting salary: £8,675 with superannuation benefits. Applicants should have a 1st or upper-2nd class honours degree in Pharmacology or Physiology. Applications, with a curriculum vitae and names of two referees, should be sent to

**Dr E. Szabadi, Department of Psychiatry, Stopford Building, The University, Manchester M13 9PT.** Closing date: 30th June, 1989. (8821)P

## STUDENTSHIPS continued

### THE UNIVERSITY OF WARWICK DEPARTMENT OF BIOLOGICAL SCIENCES **POSTGRADUATE RESEARCH STUDENTSHIPS**

Applications are invited as soon as possible for approximately 20 postgraduate studentships tenable in the fields of virology, microbiology, plant biochemistry, molecular biology and animal developmental biology from 1st October 1989 funded by the Research Councils (e.g. SERC and MRC) and other bodies. The following are examples:

- |                       |   |
|-----------------------|---|
| <b>CRC</b>            | 'The interaction of interferons with the immune response in resistance to malignant disease' (Dr. A. G. Morris)                             |
| <b>MAFF</b>           | 'Microbial growth and survival on food contact surfaces pertinent to food poisoning, spoilage and hygiene' (Dr. C. S. Dow)                  |
| <b>SERC/Earmarked</b> | 'Protein targeting in the Gram negative, plant pathogenic – <i>Erwinia carotovora</i> ' (Dr. G. P. C. Salmond)                              |
| <b>SERC/Earmarked</b> | 'Modified proteins and their role in controlling enzyme substrate specificity' (Prof. H. Dalton)  |
| <b>SERC/Earmarked</b> | 'Genetic manipulation of ricin for the development of recombinant immunotoxins' (Prof. J. M. Lord and Dr. L. M. Roberts) (two studentships) |

Applicants should have, or expect to have, a first or upper second class honours degree in an appropriate subject.

Further information can be obtained by consulting the Mini-UCCA handbook or from the **Postgraduate Admissions Tutor, Department of Biological Sciences, University of Warwick, Coventry, CV4 7AL**, (0203-523517) to whom applications, including a curriculum vitae and the names and addresses of two academic referees, should be sent indicating, where possible, the project of interest. (8813)F

## WORKSHOPS

### Carolina Workshops on GENERAL DNA TECHNOLOGY

**Sequencing & Mutagenesis**  
May 19–June 4, 1989

A general DNA techniques workshop including shotgun cloning into M13 vectors, dideoxy sequencing of random subclones and computer generation of sequence overlaps. Students may bring their own DNA for sequencing. High efficiency, oligonucleotide directed mutagenesis methods with phagemid vectors will be used for saturation mutagenesis of protein domains. Methods will be applied to a structure-function analysis of the *E. coli* maltose binding protein. Tuition is \$1600.

**Instructors:**

Alan Bankier, MRC, Cambridge,  
England

Richard Ogden, Agouron  
Institute, San Diego

Nelson Rhodes II, UNC-CH

The Program in  
Molecular Biology  
& Biotechnology

**Cloning cDNA into  
Expression Vectors**  
July 14–30, 1989

A general DNA techniques workshop in which synthesis of cDNA can cloning into lambda gt-11 are highlighted. Students may bring their own tissue or be provided with tissue from which to isolate mRNA. Students may bring antibody to screen for expression of the desired cDNA. Additional techniques include mRNA isolation, Northern transfer, Northern hybridization, and detection of proteins expressed in *E. coli*. Tuition is \$1600.

**Instructors:**

David Joseph, UNC-CH

Jerry Ware, Scripps Clinic,  
La Jolla

For further information or to apply, contact:

Dr. Susan J. Kelly, Workshop  
Coordinator

University of North Carolina at  
Chapel Hill

Program in Molecular Biology  
& Biotechnology

402 Swing Building CB 7100N  
Chapel Hill, North Carolina  
27599-7100N

CAROLINA WORKSHOPS are a series of intensive hands-on laboratory courses designed to teach cutting edge methods in DNA technology. The techniques include basic manipulations such as isolation of insert and vector DNA, ligations, electrophoretic analysis and elution from gels, blotting techniques, preparation and labeling of probes, and identification of cloned DNA. Each course provides experience in the basic techniques which serve as a solid, basic background in DNA technology. Each individual course has an identifiable theme and emphasizes in addition to the general techniques, specialized techniques such as DNA sequencing, in vitro mutagenesis, cDNA synthesis, and/or expression vectors. Students are given the opportunity to learn the techniques while also using their own starting materials or may choose to be provided with starting materials.

Many applicants to the Carolina Workshops already hold the M.D. or Ph.D. degree. Our courses are very heavy on hands-on contact with the protocols, light on lectures concerning the basics of molecular biology. Hence, a reasonable familiarity with the concepts behind DNA techniques such as those found in good texts (*e.g. Recombinant DNA: A Short Course* by Watson, Tooze, and Kurtz) is necessary to get a good yield from these courses. Experience with running these courses for seven years now indicates that both students with and students without any prior hands-on experience with molecular techniques find these courses useful. Experienced students benefit from in depth interaction with the instructors; novices learn the realities behind the innocent looking protocols. The results obtained in the Carolina Workshops can be considerable. In a recent Workshop one researcher generated 21 kb of sequence data in the Sequencing Workshop; another created 7 cDNA libraries in the cDNA Cloning Workshop.

To apply, write a brief letter describing your research interests and their relevance to the Workshop for which you apply. Please indicate your complete mailing address and telephone number. Applications received by April 7 will receive full consideration. (NW3507)V

## GRANTS & SCHOLARSHIPS

### UNIVERSITY OF EDINBURGH FACULTY OF VETERINARY MEDICINE JAMES TINDAL POSTGRADUATE SCHOLARSHIP

The Faculty will be awarding this Scholarship from October 1989 to a candidate for a research degree in the Faculty. The scholarship will comprise payment of tuition fees as well as a maintenance allowance at the University's standard rate. The award is for one year in the first instance but may be renewed up to a maximum of three years subject to satisfactory progress. Further details, application forms, and details of the Faculty's current research activities may be obtained from the **Faculty Officer, University of Edinburgh, Faculty of Veterinary Medicine, Royal (Dick) School of Veterinary Studies, Summerhall, Edinburgh EH9 1QH.**

Please quote reference: N.5651.

Application forms must be returned by 1 May 1989.

(8791)H

## ANNOUNCEMENTS

### FEBS '89 — 19th MEETING OF THE FEDERATION OF BIOCHEMICAL SOCIETIES — ROME, JULY 2/7, 1989

The Organizing Committee informs that the Secretariat numbers (Tel. 0039/6/3960341, Fax 0039/6/3964377) have changed to **TEL. 0039/6/3221806, FAX 0039/6/3222006.**

## Molecular Communication in Higher Plants 18-21 September 1989 at EMBL, Heidelberg, F. R. Germany

### Invited speakers include:

D. Baulcombe (GB-Norwich), M. Bennett (GB-Kew), M. Bevan (GB-Cambridge), T. Bisseling (NL-Wageningen), U. Bonas (D-Berlin), C. Bowler (B-Gent), F. de Bruijn (D-Köln), M. Caboche (F-Versailles), N.-H. Chua (USA-New York), A. Clarke (Australia-Melbourne), E. Coen (GB-Norwich), G. Coruzzi (USA-New York), J. Dangl (D-Köln), E. Dennis (Australia-Canberra), A. Gatenby (USA-Wilmington), W. Gerlach (Australia-Canberra), A. Gierl (D-Köln), R. Goldberg (USA-Los Angeles), W. Gruissem (USA-Berkeley), R. Hedrich (D-Göttingen), T. Hohn (CH-Basel), R. Horsch (USA-St. Louis), D. Jofuku (B-Gent), J. Jones (GB-Norwich), J. Leemans (B-Gent), P. Meyer (D-Köln), D. Mohnen (USA-Athens), T. Nelson (USA-New Haven), K. Palme (D-Köln), I. Potrykus (CH-Zürich), P. Quail (USA-Albany), E. Schäfer (D-Freiburg), A. Sievers (D-Bonn), C. Somerville (USA-East Lansing), A. Spena (D-Köln), D. van der Straeten (B-Gent), A. Trewavas (GB-Edinburgh), S. C. de Vries (NL-Wageningen), E. Weiler (D-Bochum), P. Weisbeek (NL-Utrecht), U. Wienand (D-Köln), L. Willmitzer (D-Berlin).

### There will be nine plenary sessions which will cover:

Cell-cell interactions; Differential gene expression/mutational analysis of plant function; Inter and intracellular signalling and the regulation of plant growth; Plant and environment; Plant biotechnology; Plant and microbes; Plants and viruses; Protein traffic and assembly into higher order structures; Structure, modification and expression of the nuclear genome (including novel techniques for gene isolation). The two poster sessions will allow participants to present their work.

### Registration:

The Symposium will be at the European Molecular Biology Laboratory, Heidelberg, with registration on Sunday, 17 September 1989. The registration fee, which includes daily transport to and from the EMBL, lunches, and the Symposium reception, is DM 180, for graduate students DM 90, and for participants from industry DM 360. Participants will be accommodated in the EMBL guest house and hotels in Heidelberg. The registration fee does NOT cover the cost of accommodation.

### Application:

The deadline for applicants is 16 June 1989. Applications should include a curriculum vitae and a brief description of research interests. The organizing committee will notify those who have been accepted as soon as possible after the deadline. The total number of participants will be limited to 250. Applications should be addressed to **Dr. J. Tooze, EMBO, Postfach 1022.40, D-6900 Heidelberg, F. R. Germany**. Applicants wishing to present a poster should send a 1-page abstract together with the registration fee and reply sheet after they have been accepted for participation.

### Organizing committee:

C. Leaver (Edinburgh) -Chairman-, K. Marcker (Aarhus), M. van Montagu (Ghent), I. Potrykus (Zürich), H. Saedler (Köln), F. Salamini (Köln), J. Tooze (EMBO, Heidelberg). (W5907)M

## CONFERENCES

## An International Conference NEW APPROACHES TO THE TREATMENT OF ALLERGIC DISEASE

19th/20th June 1989

Royal College of Physicians, London

This conference will provide an authoritative overview of the current status of research into the mechanisms of allergic diseases such as rhinitis, urticaria and asthma. It will also provide an up-to-date account of the current thinking on the treatment of allergic diseases and the prospects for future drug development.

### Chairmen and Speakers:

**Professor S. T. Holgate**  
Southampton General  
Hospital, UK.

**Dr. R. J. Davies**  
St. Bartholomew's Hospital, UK.

**Dr. J. Morley**  
Sandoz AG, Switzerland.

**Dr. L. G. Garland**  
The Wellcome Research  
Laboratories, UK.

**Dr. R. McMillan**  
ICI Pharmaceuticals, UK.

**Dr. B. R. Allen**  
Queen's Medical Centre  
Nottingham, UK.

**Dr. N. Barnes**  
The London Chest Hospital, UK

**Dr. L. Michel**  
Hôpital Henri Mondor, Créteil,  
France.

For further information and registration details,  
please contact:

**Renata Duke, IBC Technical Services Ltd., Bath House**  
(3rd Floor), 56 Holborn Viaduct, London EC1A 2EX  
Tel: 01-236 4080. Fax: 01-489 0849  
Telex: 888870 IBC G.

**Professor A. B. Kay**  
National Heart and Lung  
Institute, London, UK.

**Dr. D. K. Rainey**  
Fisons Pharmaceuticals, UK.

**Dr. C. De Vos**  
UCB Pharmaceutical Sector,  
Belgium.

**Dr. D. Proud**  
The Johns Hopkins University  
School of Medicine, USA.

**Dr. D. R. Stanworth**  
University of Birmingham, UK.

**Dr. H. Smith**  
Beecham Pharmaceuticals, UK.

**Dr. D. R. Buckle**  
Beecham Pharmaceuticals, UK.

# LIBRARY CONSTRUCTION IN A FLASH

## With Stratagene's Innovative Vectors And Improved Gigapack™ II Gold Packaging System

Stratagene offers a custom cDNA and genomic library service. Each library is constructed using Gigapack™ II Gold packaging extract (our newest packaging system: mcrA, mcrB, mrr-, hsdR-) and your choice of innovative cloning vectors.

### cDNA Libraries

Send us your poly (A+) enriched mRNA (we recommend the use of Stratagene's RNA isolation kit for isolating total RNA - catalog #200345). We will construct a library containing from  $1 \times 10^6$  to  $1 \times 10^7$  primary recombinant plaques depending on the integrity of the mRNA. Stratagene will also amplify your library at no extra charge. Libraries will be constructed in one of the following lambda phage vectors of your choice: The Lambda Zap®II vector, the Uni-Zap™XR vector, Lambda gt10, or Lambda gt11 vectors.

### Genomic Libraries

Send us your genomic DNA. Stratagene will perform partial or complete digests and size fractionate the DNA. Stratagene will construct a library containing from  $1 \times 10^6$  to  $1 \times 10^7$  primary recombinant plaques. If desired we will amplify your library at no extra charge. Libraries can be constructed with the Lambda FIX™II vector, the Lambda DASH™ vector, Lambda EMBL3, EMBL4, or the cosmid vector pWE.

### Pre-Constructed Libraries

Stratagene offers a large selection of pre-constructed libraries. Most are prepared with Stratagene's innovative vectors and are available for immediate delivery. Please call for information on our latest selection. Stratagene guarantees your complete satisfaction.

## FORAGING SPECIALIZATION IN ANTS

MEASURING DEVICES  
product review

**The new METTLER AT Analytical Balance  
was developed around a remarkable  
discovery: People only have two hands.**

For years people with two hands have had to operate balances designed for three.

Introducing the METTLER AT. The first analytical balance that's simple to handle.

One hand is now free to open the draft shield from the opposite side. So you don't have to twist both arms to work on the same side. Or you can let the draft shields open and close automatically. Which leaves your hands free to move your samples instead of doors.

You have a choice of configuring the draft shield so you can put your sample on from the left, the right, or even from above.

The weighing pan is close to the edge of the weighing chamber. Which for the first time allows your hand to get close to the pan.

To find out more, call us.

We'd be happy to give you a hand.

# A/D VCR Adapters

PCM-2, PCM-4,  
PCM-8 (shown)

## Store Data on a VCR

- Audio Notes
- Computer Interface
- Analog/Digital Replay
- Clock/Trigger Marking
- Wide Frequency Response
- Exceptional Input Versatility
- Low Noise (Large Dynamic Range)

Now you can store up to 8 hours of analog data on commercially available inexpensive Video Cassette Recorders (VCR's). The high performance PCM series of economical A/D VCR Adapters lets you record one to eight channels of data and recall it at any time in analog or digital form. Time or trigger marking allows precise, rapid selection of desired data on playback. Many measurement applications are now possible where more expensive and less versatile FM-type recorders were previously used.

Call or write today for more information: **800-654-5406**

# nature

30 March 1989  
Vol. 338 Issue no. 6214

In the leaf cutter ant *Acromyrmex versicolor*, queens aggregate and co-operate in the absence of kinship contrary to expectations based on kin selection theory (page 420 and News and Views). The cover shows several forager ants of this species, together with the larger queens.

## THIS WEEK

### That fusion story . . .

Comment on page 361; the background, page 364.

### Greater volume

Stephen Jay Gould on "one of the greatest causes for celebration in the history of publishing", page 385. Opinion, page 362.

### Sea change

Unexpected changes in a range of properties of water in the Black Sea lead to the suggestion that man's activities are seriously altering the ecological balance of this marine basin. Page 411.

### Disease and life style

Epidemiology implicates both hygiene and diet in diseases of Western civilization, including cancer of the colon. Environmental factors in cancer of the breast have been more difficult to identify. Commentary, page 371 and Review Article, page 389.

### Temperature rises . . .

Simply exposing a YBCuO superconductor to nitrogen can increase its transition temperature — or can it? See page 383.

### Glycine excitement

On page 425, how glycine exerts its modulatory effect on the NMDA-activated ion channel, one of the receptors for the neurotransmitter glutamate. And on page 422, the effect of the modulation demonstrated in nervous tissue. The significance of these results is discussed on page 377.

### On guard

The effect of changes in calcium concentration on potassium currents across the plasmamembranes of plant guard cell protoplasts supports the suggested role for calcium in the control of stomatal opening. Page 427.

## Meteoritic impact

The presence of 'diaplectic' glass produced without fusion is generally considered to be evidence of impact-induced shock, such as the impact of meteorites on the Earth and the Moon. But high pressure and low temperatures can produce a similar effect in the laboratory without compression due to impact. Page 413.

## Ubiquitin: new role

A new function for the protein ubiquitin is suggested by the finding that the 'tails' that extend the carboxy-termini of the products of three of the four ubiquitin genes code for essential ribosomal proteins. Pages 394 and 379.

## A 'ringing' Sun

Tree-ring and carbon-14 dating provide a chronology going back 9,600 years and raise the possibility of a 420-year fundamental period for variations of climate and solar activity, page 405.

## Paternity insurance

Mate guarding by male Idaho ground squirrels enhances a male's probability of paternity

which would otherwise be endangered by secondary matings and sperm competition. Page 418.

## Guide to Authors

Facing page 384.

# The New Dimension

## in Light Microscopy

### Zeiss Axioskop

Whenever Zeiss has turned its hand to the very fundamentals of microscopy, the results have been astounding.

This applies in particular to the Pyramids from Zeiss, the new generation of optical microscopes with new geometry and newly computed optics.

Another example: Axioskop, the microscope to meet the most exacting demands of scientific routine laboratory work.

New, high-performance IC optics for brilliant, aberration free images.

The ergonomic SI design permits the incorporation of a types of accessory equipment without impairing the integrity and performance of the total system.

Axioskop, Axioplan, Axiophot and Axiotron – the “Pyramids from Zeiss”, microscopes which point the way to the future.

IMPROVED

# GIGAPACK™ II

Packaging Extract  
mcrA<sup>-</sup>/mcrB<sup>-</sup>/mrr<sup>-</sup>/hsdR<sup>-</sup>

## Maximum Efficiencies

- Generate the most complete libraries
- Obtain those "non-clonable" inserts

Once again Stratagene breaks new ground by introducing Gigapack™ II lambda phage packaging extract. All mcrA, mcrB, mrr, and hsdR restriction activity has been eliminated from our Gigapack II extracts<sup>1</sup>. The mcrA and mcrB restriction systems of *E. coli* will damage DNA containing 5-methylcytosine. Since 5-methylcytosine occurs naturally in genomic DNA from plant and animal cells, many genomic regions are difficult or impossible to clone. Lambda phage packaging extracts generally contain residual mcrA, mcrB, mrr and hsdR activity. Gigapack II packaging extracts do not contain this activity. The elimination of mcrA and B restriction systems greatly increases the representation and size of lambda and cosmid genomic libraries, especially when using DNA from species having a substantial degree of methylation. Moreover, there are genomic regions in most species that are highly methylated and thus difficult or impossible to clone. Elimination of hsdR restriction activity allows the cloning of inserts bearing Eco K restriction sites, which are not protected by 5-methylcytosine.

Gigapack II packaging extract is also useful for cloning cDNA that has been synthesized using 5-methylcytosine, such as with Stratagene's new unidirectional ZAP™ cDNA synthesis kit. Gigapack II is simple to use and is available in the following kits:

NAME	FEATURES	REACTIONS	CAT#
Gigapack II Gold	2x10 <sup>9</sup> pfu/μg λ DNA	11	20021
Gigapack II Plus	1x10 <sup>9</sup> pfu/μg λ DNA	11	20021
Gigapack II XL	Designed for size selective packaging	11	20021

New restriction minus *E. coli* strains are also available further improve library representation. The mcrA<sup>-</sup> and mcrB<sup>-</sup> P2 lysogen strain, P2PLK17, permits use of the efficient Spi<sup>-</sup> selection system for low levels of nonrecombinant background clones in genomic library preparation. PLK-F<sup>-</sup> and PLK17 are available for generating efficient unidirectional cDNA expression or subtraction libraries.

Gigapack II is even more effective with methylated DNA using Stratagene's new restriction minus plating hosts CPLK and P2CPLK, which are derived from *E. coli*

<sup>1</sup>Kretz, P.L. and Short, J.M. (1989) *Strategies* Vol. 2 No. 2

NAME	CHARACTERISTICS	CAT#

Whatever your application, a

Pipettes from  Labsystems

# pipette's the answer.

Multichannels now available

From single-channel and multichannel pipettes through to the unique Dilute Labsystems' Finnpipette range of liquid handling equipment offers you the widest choice on the market. The Digitals shown here for example go right down to 0.5  $\mu$ l. All with fully validated accuracy and precision. And because we understand the nature of your work, easy and above all comfortable use. To ensure best results we also supply a full range of quality disposables and accessories. So whatever field you're working in – clinical chemistry, microbiology, genetech technology – take a tip and start using Finnpipettes.

Ease of use and comfort – Simply turn the thumb button. It clicks to the desired volume. No scales to align. Instead check the clear, easy-to-read digital display and start pipetting. Without straining your hand ... even after hours of use – thanks to the lightness and comfort common to all Finnpipettes.

Safety and durability – The streamlined unobtrusive tip ejector ensures safety even with biohazardous materials. And also prevents accidental detipping. Durable construction space-age plastics mean longer bench life.

Accuracy and precision – Each Finn timer arrives ready for use with its own accuracy validation certificate. What's more, recalibration can be carried out in your laboratory, quick and easily.

Full range of quality disposables – for best results we recommend using Finntips. Made from clear contamination-free plastic, they are available vertically packed for added convenience in boxes, or bulk-packed in economics.

*Identification and phenotyping*

# Just add H<sub>2</sub>O

You might expect the companies that have introduced techniques and products such as isoelectric focusing and *PhastSystem*<sup>TM</sup> to supply everything you'll ever need in advanced electrophoretic technology.

Well, not quite. After dedicating more than 20 years to electrophoresis development, we're still looking for better, more innovative ways to help you manage biomolecules. *And we're finding them.* In protein and DNA electrophoresis, for example, Pharmacia LKB's range of media and

instruments is in a class by itself. Have a look.

For protein biochemists, we offer the fast and reproducible *PhastSystem* and an extensive range of precast gels for SDS-PAGE, IEF and more. Then there's isoelectric focusing using the *Multiphor II*® system and *Ampholine*® or *Pharmalyte*® carrier ampholytes ... or precast *Ampholine* PAG plates ... or *Immobiline*™ DryPlates.

*Ultrascan XL*™ laser densitometer and *GelScan XL*™ software provide advanced, computer-aided evaluation.

For molecular biologists, *Pulsaphor*™ and *VacuGene*™ have become industry standards in the areas of pulsed field electrophoresis and vacuum blotting of nucleic acids. We also offer a range of quality reagents for molecular biology. And *MacroGene*™ workstation simplifies DNA sequencing and analysis.

In protein and peptide research, as well as molecular biology – Pharmacia LKB offers total solutions based on electrophoresis, as well as standard and high performance chromatography.

Ask for a copy of our new Electrophoresis Catalogue '89. It contains everything you will need for protein and nucleic acid electrophoresis. Just add water ... and electricity.

## Academy elections in a muddle

The Soviet Academy of Sciences has been made a laughing-stock by the muddle over its constituency election for the Supreme Soviet. But the difficulty should have been anticipated.

THE continuing pantomime (see page 364) of the failure of the Soviet Academy of Sciences to elect a score of people as its representatives in the new Chamber of the People's Deputies is neither a surprise nor a criticism of the academy. On the contrary, it may more properly be regarded as a sign of grace. The academy's failure even to nominate enough people to fill the 25 places it had been offered in the new chamber (in the end, there were only 23 nominees, so that five places were relinquished) is a measure of the diversity of opinion within the academy, and of its members' willingness to behave as they believe. Is that not a virtue, rather than the opposite?

Even so, the conduct of the election, and its outcome, will not enhance the academy's reputation within the Soviet Union or elsewhere. Nor will it do much for the reputation of the Soviet electoral system, hastily devised last year as part of the cutting edge of *perestroika*. There are too many wheels within wheels for anybody's comfort. One difficulty is that there are too many kinds of constituencies. Some are geographical, some geographical constituencies include groups of others, while other constituencies are professional (such as the academy) or defined by other special interests (such as the company of Soviet philatelists). Another difficulty is that the rules by which professional and other societies have approached the process of election have been vague, to say the least.

Within the academy, the first step (in January) was a kind of popularity contest in which individual institutes put forward names for nomination. Sakharov and Sagdeev (in that order) came out on top, but then failed to win half the votes that might have been cast at the special conference a few weeks later. Now, 15 out of the 23 nominees still in the race have fallen for the same reason, no doubt victims of the advertised determination of those who wished to vote for Sakharov and Sagdeev to vote against all other candidates. Why, despite all the secret ballots, should candidates overwhelmingly popular at one stage of the election fail to be elected at the next? The immediate explanation is that the electorate changed (and narrowed) between the beginning of January and the end. And the explanation of that is that the academy, while seeking to give democratic processes an airing, did not dare go far down the road of one man, one vote.

Yet the Chamber of Deputies being elected is an important part of a new and more democratic system. Although it will meet only infrequently, it will have the crucial task of choosing the new Supreme Soviet, intended to become a full-time legislature under Mr Mikhail Gorbachev himself, who will be its president. It will have influence, even power. All the more reason why it should seem legitimate. Perhaps its first task should be to revise the law under which it is being elected, in the process abolishing the professional constituencies and the underlying principle of "most men, one vote: some men, two votes".

For the Soviet academy, the lessons to be drawn from this affair go even deeper. In the Soviet Union now, elections for institute directors, laboratory heads and others are all the rage. But on a matter such as the election of people to the Chamber of Deputies, which has nothing to do with the management of the academy's own over-complicated business, it is absurd that the academy should have canvassed the wishes of those working in its institutes and then have allowed them to be denied. If laboratory workers want Sakharov and Sagdeev to represent them, why should they not have their way? □

## Cold (con)fusion

Reports that an account of cold nuclear fusion is soon to appear in this journal are premature.

INCREASINGLY alert coverage of science by newspapers, taken as a sign of increasing public interest, is something that readers of this journal should applaud. But when scientists find themselves reading about their colleagues' discoveries in newspaper columns before anything has been submitted, let alone accepted or published, in a research journal, there is cause to be worried. No one was more surprised than the editors of *Nature* to learn, on reading last Friday's *Wall Street Journal* that two papers on room-temperature nuclear fusion (see page 364) would probably appear simultaneously in this journal, perhaps in May.

That editors of scientific journals are annoyed by this kind of event is due neither to sour grapes nor to a cabalistic devotion to secrecy. The procedure of peer-

review, slow and irksome as it sometimes can be, has evolved to protect not only journals but scientists and science itself from a barrage of unsubstantiated claims which later have to be withdrawn. The more outlandish the claim, the less likely authors seem willing to submit to careful scrutiny by knowledgeable people working in related areas. There are understandable reasons for this reticence. It is the rare piece of research indeed that both flies in the face of accepted wisdom and is so compellingly correct that its significance is instantly recognized. Authors with unique or bizarre approaches to problems may feel that they have no true peers who can evaluate their work, and feel more conventional reviewer's mouths are already shaping the word "no" before they give the paper much attention. But it must also be said that most unbelievable claims turn out to be just that, and reviewers can be forgiven for perceiving this quickly.

But unsubstantiated claims often make interesting news, which journalists have a duty to report even if they do so sceptically. Unlike other 'news' stories that appear in daily newspapers, 'science news' stories have no clear date when they become news worth printing. Is a scientific discovery news from the day it is made, the day it is submitted to a journal, the day the journal accepts it, or the day it is published? Reasonable people will differ on which is the correct answer.

Even with the best of luck and planning, this journal cannot take a scientific paper from receipt to publication in less than about a month. Last week's issue contains two examples, concerning the new pulsar in supernova 1987A, in which the researchers concerned were able to keep quiet for the required few weeks. But there are those who feel compelled, either for money or fame, to ballyhoo discoveries before anyone can reasonably judge their merits. Superconductors, AIDS treatments and new energy sources bring behind them patent lawyers and venture capitalists, to whom breaking the press embargo of an academic journal probably seems a negligible misdemeanour.

But patents that turn out to be worthless and investments that disappear may demonstrate the value of cautious peer-review to those who now think of it as a fusty institution much loved by pedants. The sceptical tone adopted in many newspaper accounts of cold fusion, and the emphasis given to the fact that no paper has yet been accepted for publication in any scientific journal, indicates that journalists (who learn nearly as fast as they write) appreciate the pitfalls. Many learned a lesson two years ago, when reports of superconductivity at increasingly incredible temperatures were appearing daily. It did not take long for science writers to realize something was amiss, and after seeking professional advice they began asking for specific evidence of superconductivity, such as magnetic-flux expulsion, in addition to claims of sudden drops in resistance. An obvious need existing, peer-review was spontaneously re-invented. □

## Words by machine

Computerizing the *OED* should help its publishers to remedy the dictionary's most obvious defects.

STEPHEN J. Gould is right to welcome the new edition of the *Oxford English Dictionary* as a landmark in the intellectual life of the English-speaking world (see page 385). It may be even more than that. That the dictionary of a language should be constructed on historical principles, recording all the usages of all words without the disparagement of any, was in itself a radical notion even further out of tune with the mood of Victorian England when the dictionary was begun than with the still-prescriptive inclinations of our times. The result, as Oxford University Press is eager to proclaim, is not so much a dictionary as a living record of the changing English language, or at least of that part of it used by the British. Will the appearance of the new edition of the dictionary spark the imitation by other-tongued linguistic chauvinists that could further augment its value by providing comparative records of how languages evolve?

For the British (and for the dictionary's publishers), several questions arise. The dictionary now published as ink on paper is not the real thing, but a first approximation to it. Words and meanings are accumulating all the time. The publishers plan to put out another version in a few years on compact disks readable by laser. No doubt successive versions will be numbered much as software manufacturers sell new versions of their products, in a decimal notation. Because the dictionary is built on historical principles, that should not be as confusing as it seems: new versions will include their predecessors. But, now that the Oxford University Press has survived its first serious brush with computer technology, there is also a case for making the dictionary accessible on-line. There is also now an opportunity to use the new technology for capturing examples of the use of new words, or of old words in new meanings, whose compilation has been the back-breaking and sometimes disheartening part of the labours of the past century. It is not merely that the publishers will thereby be saved time and money, but that they will then be less likely to neglect the maintenance of a important scholarly resource than they were in the 1930s, when work on the dictionary was halted for a quarter of a century.

That is also how best to make progress towards remedying even the new edition's most obvious deficiencies, of which there are two. First, the dictionary's treatment of even common usages in science is hesitant at best, as may be told from the article on "anti-particle" in the new edition. Second, it is too dependent on British sources. When everything had to be done by hand, there may have been no choice. Now there is a chance to make it into an English dictionary in the full sense. That should not be neglected. □

# Shake-up in store for Britain's biologists

- New organization eliminates fragmentation
- Single funding source proposed for all biology

## London

THE biological sciences in Britain's universities are underfunded, short of manpower, and teaching and research are "undesirably fragmented", according to a committee set up by the Universities Grants Committee (UGC) to advise on how academic biology could be 'rationalized'. The results of the review have been shrouded in secrecy until now, and there is likely to be heated debate about the conclusions at a meeting this week of the heads of Britain's biology departments.

Similar reviews of chemistry and physics last year concluded that to maintain quality with the limited funds available resources should be concentrated in large departments—those with at least 20 full-time staff. But the biology committee concludes that resources for biology must expand. Professor Richard Southwood of the University of Oxford, who chaired the UGC committee, says biology will be the "leading science of the twenty-first century". He complains that biology has always been underfunded because when interest in the subject increased in the 1970s, a period of university expansion had ended and there were increasing constraints on growth. An injection of funds is now necessary to compensate for this, he says.

The committee says that the main problem facing biology is the fragmentation of teaching, research and of the funding mechanisms. To eliminate fragmentation in support, the report recommends money for biology be provided from one research council instead of the current four. Most support for biology is now channelled through the Science and Engineering Council (SERC). But to avoid competition with the expensive demands of the physical sciences and engineering, the responsibility for biology should not be vested in SERC but in a new biological sciences council.

For research and teaching, the report recommends that all biology departments be grouped into a single organization, within which there should be two distinct subgroups. One, termed M, would focus on molecular sciences, including biophysics, biotechnology, physical biochemistry and molecular genetics. The other, called B, would focus on traditional areas of biology such as physiology, ecology, entomology and evolutionary studies. Most biologists do not dispute that more integration of their departments is desirable, but the M/B

idea is nonetheless controversial. To ensure that all facets of biology are covered in each department, the committee says there would need to be 5 research groups each with at least 4 members of staff, so each department would contain at least 20 members of staff.

Meeting the requirements of size and covering the defined areas at the same time would require "an enormous amount of restructuring" in universities, said Professor Christopher Arme of the University of Keele, though he agrees that larger departments than exist at present would be desirable. Others have a different view. Professor David Cove of the University of Leeds argues that small departments can be more efficient than large ones, and a greater amount of personal attention to students is rewarded with a better quality of student.

Southwood stresses that closure of any biology department would be short-sighted. The predicted demographic dip in the 1990s leading to fewer young people of university age is a misleading indicator of future demand. There is likely to be an acute shortage of suitable personnel for posts in biology in universities and research-council institutes in the future, says the report. It supports the schemes of the UGC and the Royal Society to tackle this problem, but warns against central planning in relation to subject and place of study.

One of the concerns of the committee is that traditional areas of biology are increasingly being neglected, and it believes that there should be an equal number of M and B departments. Undergraduates would take a three-year degree course in one department, but should have a basic understanding of the biology studied by the other groups. The committee also warns against central planning in distribution of research funds. It is impossible for committees to identify topics that will lead to significant advances in the future, and best value for money will be obtained by research funds allocated by heads of departments. A spectrum of mechanisms for distributing funds should be pyramidal, with a base of many project grants and relatively few large interdisciplinary research centres. Though the government is now considering separating the allocation of funds for teaching and research in Britain, the committee warns against taking any responsibility for research funds away from the universities.

**Christine McGourty**

## NEWS IN BRIEF

### Alaskan oil spill

#### Washington

THE oil tanker *Exxon Valdez* last week struck a reef and spilled some 11 million gallons of crude oil into Prince William sound off the south coast of Alaska. The spill is being called the worst in North American history. The tanker had just left the port of Valdez, the south terminus of the Trans-Alaska Pipeline and was carrying 53 million gallons of oil. Clean-up crews are trying to contain the spill which threatens severe disruption to the local ecosystem. J.P.

### Better health ahead

#### Sydney

A NATIONAL strategy for Aboriginal health, released at the annual meeting of health ministers last week, is the first attempt in ten years to deal with the health problems of that population. Australia's 228,000 Aborigines suffer from poorer health and a lower life-expectancy than the general population. The World Health Organisation said last year that Aborigines have the worst reported standard of health of any indigenous people. The government's strategy includes plans for upgrading health services, providing more health training and educational programmes, and transferring basic Aboriginal health services from the state governments to the Aboriginal health community. The recommendations, if implemented, are expected to cost A\$417 million. T.E.

### Hair-raising scheme

#### New Delhi

HUMAN hair is one of India's resources that has heretofore gone to waste. But an Indian and a Japanese company have now formed a partnership to turn what was discarded into profit.

Hair is a potentially profitable source of amino acids. Under the new arrangement, Union Bros of Japan will supply expertise, equipment and part of the finance for a \$10-million processing plant being set up at Pondicherry in south India. The plant will consume 1,200 tonnes of human hair a year, turning it into 80 tonnes of L-cysteine, 24 tonnes of L-tyrosine and 1,400 tonnes of dry powder containing as many as 19 amino acids. The products are extensively used in the pharmaceutical, food-processing and cosmetic industries. The company expects to make 25 per cent profit and Japan will purchase the entire output for 8 years. Human hair has become an important raw material for amino acids after whaling restrictions made that source scarce. Apart from barbers' shops, the biggest source of human hair in India is the temples, where Hindus shave their heads as a religious custom. One temple in Tirupati Inandhra Pradesh collects 4,000 tonnes of hair a year. K.S.J.

## Cold results from Utah

### Washington

AN announcement last week by the University of Utah in Salt Lake City that physicists there had achieved nuclear fusion in a test tube at room temperature has been followed by a flurry of speculation about not only the strange science involved but also the peculiar publicity given to it.

The technique involves nothing more complicated than electrochemistry. Current is passed through a palladium electrode immersed in a solution of various salts in deuterated water. Over a period of many hours, deuterium atoms are absorbed by the palladium lattice in such numbers that some of them fuse, forming tritium or helium-3, simply because of their proximity. A return of four watts of heat from one watt of electricity was reportedly obtained when current was passed for a total of 100 hours.

According to James Brophy, vice president for research at the University of Utah, the decision to announce the work in preliminary form at a press conference last Thursday, before a paper had been accepted by a scientific journal, was a response to press enquiries. But the university press office had previously contacted several science reporters and encouraged them to attend.

A statement by the University of Utah that results "will appear in the scientific literature in May", coupled with a report in last Thursday's *Wall Street Journal* that papers had been submitted to *Nature*, provoked numerous telephone calls to *Nature*'s Washington office enquiring whether we had accepted or were about to publish one or more papers. (The answer is no.) Meanwhile, a group at Brigham Young University in Provo, Utah, led by Steven E. Jones, has refused to say whether they have obtained similar results.

Enthusiasm over the claim has been tempered with a good deal of scepticism, not only due to the lack so far of a detailed account but also because the history of fusion research has been regularly punctuated by 'breakthroughs'. The new claim bears some similarity to muon-catalysed fusion, in which the substitution of a muon for an electron in heavy hydrogen shrinks the size of the molecule enough for spontaneous fusion of the two deuterons to occur. Reasonable rates have been achieved in small-scale experiments, but as an energy-producing method muon fusion is no nearer success than any other technique. The University of Utah has applied for a patent on its technique, but Jones says only "don't sell your oil stocks yet". □

## Academy starts over again

### Moscow

AT the general meeting last week of the Academy of Sciences of the USSR, only 8 of 20 delegates were elected to the All-Union Congress, from which delegates will ultimately be elected to the Supreme Soviet of the USSR. The Academy's election process will now have to begin again.

The normal election procedure was complicated by the fact that after an extended plenum of the leading bodies of the Academy on 18 January, just 23 candidates for the 20 delegates out of 130 candidates proposed by research teams at academic institutions were chosen (see *Nature* 337, 293; 1989). The failure to nominate those scientists receiving the greatest popular support—including Academicians Andrei Sakharov and Roald Sagdeev—evoked particular discontent. A lobby was set up for the democratic election of People's Deputies from the Academy of Sciences of the USSR, which held a protest meeting in front of the Academy Praesidium's building in Moscow, and organized what amounted to a boycott of the election of the nominated candidates.

According to the law, additional elections have to be held to fill the remaining 12 delegates within the next two months. The new election process began during last week's general meeting, when procedures and potential candidates were discussed. Describing the outcome of the elections in his speech at the conference, Sakharov emphasized that emotions were running so high not because "Sakharov was not nominated, but because the role of the research institutions was ignored".

Academician G.I. Marchuk, president of the Academy, explained the current election phenomenon by saying that "all of Soviet society, including the Academy, is going through a historical moment—the transition to people's power has started in the USSR in earnest. The main point is that the elected deputies will represent not just the interests of the Academy but also and above all the interests of the social development of the nation as a whole."

Voting procedures now call for the 15 unsuccessful candidates to be asked to agree to run again. In addition, many scientists from the previous list suggested by various institutes, as well as new names, were mentioned. Judging by the response of the audience, the following scientists should be on the list of new candidates: Academician Stanislav Shatalin, an economist; Academician Vitaly Ginsburg, a physicist; and the economist Nikolai Shimeley. New elections will probably be held next month.

The conference decided that new candidates will be nominated by the Praesidium of the Academy of Sciences of the USSR. This responsibility has now been vested in it after the extended plenum of the leading bodies of the Academy failed to rise to the occasion. The members of the former election commission of the Academy of Sciences on the election of People's Deputies have resigned, and a new commission will be formed. The date for a new election conference has not yet been fixed. Importantly, the voting will be by secret ballot at meetings of research associates of academic institutes.

### WEATHER FORECASTING

## Precipitation precipitates complaints

### Sydney

AN insufficient number of weather stations are being blamed for Australian weather forecasters' failure to provide early warning of torrential rains that flooded parts of central Australia, causing significant stock losses. Rains have been particularly heavy in Australia this year. At Broken Hill, in western New South Wales, 180 millimetres of rain fell in a slightly more than 24 hours, the heaviest fall that had been recorded since 1973. Storm warnings by the Department of Meteorology came on the morning of the fall, too late for some farmers.

A reduction in staff salaries and productivity costs means much of Australia's weather remains undetected. "We have a country the size of the United States with one tenth its population. The quality of

our meteorological services is related to the observational networks we can afford", said Bill Downey, assistant executive director for the Australian Bureau of Meteorology.

Peter Noar, assistant director of weather services, acknowledges that a full network of a couple of hundred observation stations is needed. Some help may come from plans to expand land-based automatic weather stations and improve the network for aviation forecasting.

But the problems at Broken Hill are threatening to get worse before they get better. The Civil Aviation Authority airport observation station may close, forcing the Bureau of Meteorology to try to come up with sufficient funds to open its own station in Broken Hill.

Tania Ewing

## SPACE STATION

## REMOTE SENSING

# Banging the Freedom drum

## Washington

NATIONAL Aeronautics and Space Administration (NASA) officials like to say that no matter what objectives are chosen by the United States for space activities in the twenty-first century, "all roads begin with the space station Freedom". But as NASA pleads its case before a budget-conscious Congress, Freedom's \$16,800-million price tag practically guarantees that its own road into space will be a rocky one.

Now set to be deployed in the mid-1990s, the space-station programme is building momentum. Last September, Canada and the European Space Agency signed formal participation agreements (see *Nature* 335, 480; 1988), and earlier this month Japan signed a memorandum of understanding. Altogether, NASA's foreign partners will contribute \$8,000 million to the project.

President George Bush is an enthusiastic proponent of the space station. Nervous about the cost, Congress last year appropriated \$900 million for the space station, but ordered \$515 million to be held back until 15 May this year so the new president could decide whether to proceed. President Bush has already indicated that the money will be released for the space station.

This year, NASA is requesting \$2,050 million for its space-station activities. Three-quarters of that money will go to the four aerospace companies with which NASA signed contracts last September to build major elements of the station. Boeing is developing the crew living quarters and logistic elements; McDonnell Douglas is pursuing the central truss structure and resource nodes; General Electric is developing the polar platform and attached payload accommodations on the main station; and Rocketdyne is developing the power systems.

For its part, Congress is enthusiastic about the idea of the space station, but budgetary concerns make any new and expensive project vulnerable. The word around Congress is that as much as \$1,000 million may be cut from NASA's total 1990 budget request of \$13,300 million, and some of that is bound to come from the space station.

But space-station officials are already feeling pinched, and have warned that further cuts could be devastating. NASA has not been able to find funds for nearly a third of the 2,644 posts authorized for the programme. At a hearing on 16 March before the Senate Commerce, Science and Transportation Subcommittee on Science, Technology and Space, NASA Associate Administrator for the Office of Space Station James Odom

testified that "virtually any cut would do major hurt, and a significant cut would be tantamount to killing the programme". Odom also warned that backing out on NASA's commitments to its foreign partners would also have devastating effects.

Launching the space station is planned to take 20 space-shuttle flights, the first of which is now scheduled for 1995. Human occupancy should be possible after the fourth shuttle flight, and a permanent crew can stay on board after flight 13.

The space station's attached science payloads — now likely to include a gamma-ray/cosmic-ray focusing device called Astromag and a cosmic dust sampler — are intended for flight 7, an early

Installing equipment in Boeing's mock-up of Freedom's living quarters.

flight that supporters say is indicative of NASA's commitment to doing science on board the space station. The launch schedule for the flights is based on current shuttle lift capabilities, and a new advanced solid rocket motor, once it becomes available, could speed up the process.

A decision to move forward with shuttle-C, a cargo-only version of the shuttle devised as an alternative option, would also be a boon for the space station, but so far the administration has shown little support for this plan.

Coordinating the development of hardware with that of scientific instruments so that both will be ready to fly on time will be a tricky business. As an example, General Electric has already begun work on the polar platform, but funding for the platform instruments, which have already been selected, will not be formally requested until the 1991 fiscal year. Last-minute modifications to spacecraft hardware to accommodate instruments can be extremely expensive, and can cause delays.

Although NASA has agreed with the

## On-again, off-again Landsats on again

### Washington

LANDSATS 4 and 5 are back in business — for the moment. The Earth Observation Satellite Company (EOSAT) announced on 15 March that the shut down order issued by the National Oceanic and Atmospheric Administration (NOAA) had been rescinded.

EOSAT, which operates the two Earth remote sensing satellites for NOAA, had begun shut down procedures that would have terminated Landsat operations at the end of the month (see *Nature* 338, 194; 16 March 1989).

Details of the financial rescue package have not been revealed, but EOSAT says it costs \$9.4 million to operate the two Landsat spacecraft. NOAA officials will only say that the reprieve will last at least until the Bush Administration completes a review of the programme now under way.

The rescue effort was coordinated by the new National Space Council chaired by Vice-President Dan Quayle. Members of Congress have reported that their offices have been inundated by letters asking that money be spent to keep the Landsats alive.

Joseph Palca

White House Office of Management and Budget to cap spending on the space station at \$16,800 million, several elements of the station, such as operations costs, facilities, launch costs, communications support and several new features including an emergency crew escape vehicle, are not covered by the cap. Other programmes at NASA have been cut back in order to provide adequate money for necessary space-station development and activities.

There has long been tension between space scientists and those favouring manned space activities. Station chief scientist John Bartoe acknowledges that selling the station solely as a tool for science is untenable, but that it can be useful for scientists once they learn its capabilities. It seems likely that the successor to James Fletcher, who has announced his resignation as NASA administrator, will continue the strong support NASA has traditionally provided to the manned space programme.

Proponents of the space station are trying to secure the high ground in their efforts on behalf of the space station. At the Senate hearing earlier this month, Senator Al Gore (Democrat, Tennessee) set the tone for the coming Congressional debate that will make opponents of the space station squirm: "The choice facing us this year is not just between moving ahead with the space station or not, but between continuing leadership in space and abdication and decline."

Joseph Palca

## Transgenic sticky issues

### Washington

ANIMAL rights, the release of genetically engineered organisms into the environment, and the effects of large agribusiness companies on the farming industry are the real issues behind the debate over the patenting of animals, according to a report\* released last week by the US Congress's Office of Technology Assessment (OTA). Existing regulations can be adapted to address most of the practical considerations of animal patenting, such as whether farmers should pay royalty fees for breeding patented livestock. But the ethical question of whether or not transgenic animals should be subject to patents is a question that may need further clarification, OTA says.

Congress has heard both sides of the debate since the patent office declared in early 1987 that it would not reject patent applications on the sole basis that the invention for which the patent was being sought was an animal. The granting of the first patent for a higher life form last year — to Harvard University, for a transgenic mouse containing human on-

cogenes (see *Nature* 332, 668; 1988) — heated up the exchange between patent proponents and those who asserted that animal patenting would lead to animal suffering and higher costs for farmers.

But attempts in the past two years to pass legislation to halt the patenting of additional animals until the ramifications could be worked out — and specifically to exempt researchers and farmers from royalty payment requirements — have floundered. The Animal Legal Defense Fund has also lost the first round in a court battle to overturn the patent office's decision to patent animals.

In the meantime, 44 patent applications covering animals have piled up at the patent office, and the exclusive

Du Pont's OncoMouse, the only patented animal so far.

licensee of Harvard's patent, Du Pont, is taking orders for its \$50-a-piece OncoMouse, which it plans to begin shipping in May. Other companies are not waiting for patent protection to develop profit-making genetically engineered animals. Integrated Genetics has formed a collaboration with Tufts University to develop herds of cows capable of excreting human proteins in their milk, and the company Transgenic Sciences has just been formed, and intends to develop animal breeds which produce valuable pharmaceuticals.

Representative Robert Kastenmeier (Democrat, Wisconsin) last week reintroduced bills he put before Congress last year that would create a transgenic animal advisory committee within the Department of Agriculture which would authorize permits to field-test transgenic animals. Kastenmeier's bills also specifically exempt farmers and researchers from paying royalties on patented animals. Kastenmeier says he hopes biotechnology companies and opponents of animal patenting can work out their differences, an acceptable compromise, but

\*New Developments in Biotechnology — Patenting Life, Office of Technology Assessment, Washington DC, 1989.

## New carp park ahead

### Washington

THE biotechnology review board of the United States Department of Agriculture last week approved the first field-test involving a genetically-engineered fish. Researchers at Auburn University in Alabama have been given permission to introduce carp which contain trout growth hormone genes into a test pond at the university.

The carp were developed through a collaboration between researchers at Auburn, and at Johns Hopkins University in Maryland. Carp containing the trout genes have been shown in the laboratory to grow significantly larger than normal carp, a finding that could have commercial significance for fish farming.

The carp will be kept in a contained pond, with a series of barriers to prevent their escape into open water. As an added precaution, a mechanism has been developed to introduce poison into the water should a fish manage to get beyond one of the barriers.

The Auburn carp is the first transgenic animal to be approved for release into the environment by the Agricultural Biotechnology Research Advisory Committee, which has been charged with developing guidelines for reviewing field-test applications from researchers working under Department of Agriculture grants. The finishing touches are now being put to the committee's guidelines, which should be published in the Federal Register for public comment within the next two months.

The Department of Agriculture is opposed to legislation introduced last week by Representative Robert Kastenmeier (Democrat, Wisconsin) which would require it to set up a separate review board to grant formal permits for field-tests of transgenic animals. Daniel Jones from the Department's Office of Agricultural Biotechnology says that laws already on the books should cover transgenics, with some "fine-tuning" from the new guidelines. Jones says the guidelines will parallel those covering recombinant molecules developed by the National Institutes of Health: they will be compulsory for academic grantees, and industrial researchers are expected to adhere to them voluntarily.

Carol Ezzell

that he will support a halt to animal patenting if the means to address the sticky issues surrounding such patents is not put in place.

The Congressmen who proposed a moratorium on the patenting of animals last year, Representative Charlie Rose (Democrat, North Carolina) and Senator Mark Hatfield (Republican, Oregon), have no plans to introduce their bills again this year.

Carol Ezzell

### CHEMISTRY

## NERC finds British chemistry ailing

### London

CHEMISTRY in Britain is suffering from insufficient investment, inadequate equipment and poor dissemination within the research community of information on facilities available. Those are the main conclusions of a committee set up by the Natural Environment Research Council (NERC) to review the health of chemistry. The report, published this week, concludes that facilities are outdated, and most researchers feel they are lagging far behind their counterparts in other European countries and in the United States. The committee says that because much of the equipment in universities and NERC institutes is old, slow and insensitive, the quality and quantity of data is suffering. This in turn may be leading to the loss of commissioned research contracts.

To remain competitive, Britain must have well-equipped, state-of-the-art laboratories, and this will require a substantial programme of investment in chemical equipment, says the committee. Its report points out that although the cost of equipment is increasing faster than the rate of inflation, its speed and sensitivity are increasing even more rapidly, so the cost-effectiveness of new equipment is improving in real terms. At present, even the equipment available is used insufficiently because of severe constraints on travel and subsistence budgets.

Christine McGourty

## CHERNOBYL

# Soviet data made public

London

RADIOACTIVE contamination from Chernobyl is still "an acute technical and social problem" likely to persist for a considerable time, according to Dr Yuri Izrael, chairman of the State Committee for Hydrometeorology, writing in *Pravda* last week. In a full-page article, he presented the first figures and maps for the whole area of the Soviet Union affected, comprehensively extending the data for Byelorussia given at a public meeting in Minsk last month (see *Nature* 337, 683; 28 February 1989).

The release of these data is an important development, a departure from the policy described by Kiev radio earlier this month as the "tranquillizing" of the population. Contrary to the impression conveyed at Minsk that the collection of data had only just been completed, Izrael also says that the collection of data began on 26 April 1986, the day after the accident, and that a generalized map covering a 60- by 40-km region showing contours of gamma-radiation was available on 10 May that year, in time to guide the evacuation of people from contaminated zones.

In the first few days after the accident, Izrael says, the first 2 milliroentgen per hour contour enclosed about 200,000 km<sup>2</sup> of Soviet territory, with islands of contamination as far away as the Kola Peninsula in the far north, Ivano-Frankovsk in the south-west and the Caucasus in the south-east.

"Massive" testing of soil samples began in June 1986, when exceptionally high proportions of the long-lived isotopes caesium-134 and caesium-137 were found. But Izrael says that the lifetime exposure limit of 35 rem of external radiation was applied to the caesium-

contaminated areas only in November 1988, leading to the evacuation of a further 20 villages in Byelorussia.

Pollution of rivers and reservoirs remained "within the limits of the agreed norms" in the months after the accident, according to Izrael, who says that total beta-activity amounted to between 1 and  $6 \times 10^{-9}$  curie per litre during the first two months. (The safety limit was  $10^{-8}$  curie per litre.) During the spring floods of 1987, Izrael says, even the rivers with radiation 'hotspots' in their catchment areas were well below the limit.

Further aerial and ground surveys carried out in 1988 are said to have revealed substantial changes of the contours. At present, Izrael says, for caesium-137 the 15 curie per km<sup>2</sup> contour encloses some 10,000 km<sup>2</sup>, of which some 3,500 km<sup>2</sup> have been evacuated, while the remainder has a population of 230,000 people. In the town of Slatytych, built for Chernobyl workers after the accident, radiation levels (0.013 to 0.03 milliroentgen per hour) are close to the natural background, although there are some hotspots in the surrounding forests which nevertheless do not exceed the safety limits.

Although Izrael's sympathy for the new anti-nuclear groups in the Soviet Union is clearly muted, he concedes that the decision to close the two Armenian reactors (at Yerevan, one last month and one this) was "quite understandable". But he concludes that, with the threat of the greenhouse effect, nuclear generation is the "most promising" form of energy. The lessons of Chernobyl, he says, imply that the operation of existing nuclear reactors is "many times", and of future stations, "many orders of magnitude", safer than in the past. **Vera Rich**

## ABORTION

# French drug under attack

Paris

THE controversial abortion pill RU-486, which was approved by the French Health Ministry for use in abortion clinics last year amid angry opposition, is again under attack (see *Nature* 336, 4; 1988). Dr John Willke, of the US National Right to Life Coalition, is in Europe for the annual meeting of the International Federation for the Right to Life in Brussels. Before the meeting he met the medical research director of Roussel-UCLAF, the company that makes the drug, and suggested that the company's products could be boycotted in the United States if the drug is not withdrawn.

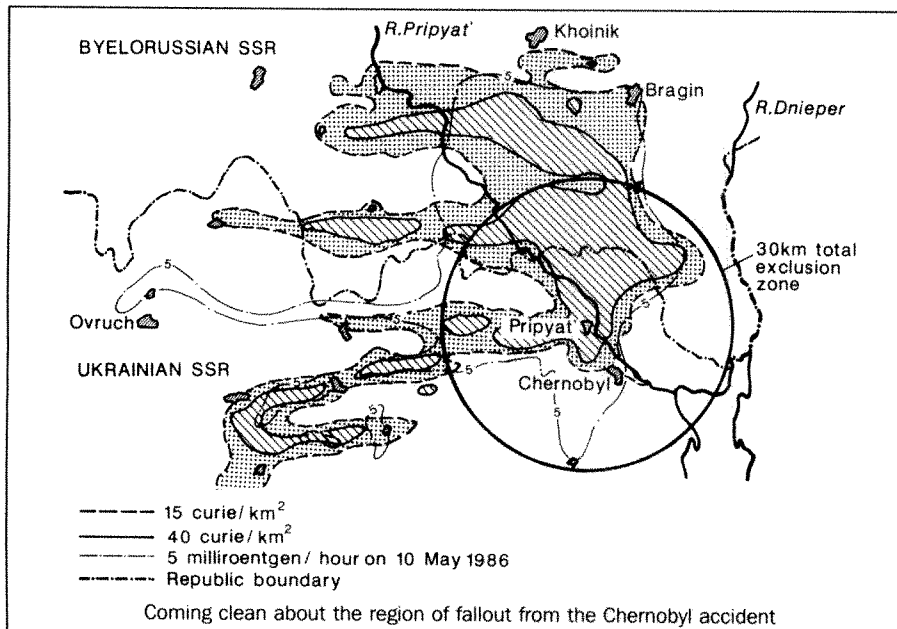

France is the only country to have legalized the use of RU-486 for abortion, and the drug is administered only under strict medical supervision and only in association with prostaglandins. In October last year, Roussel-UCLAF suspended sales of the drug after some of its senior employees and their families received anonymous death threats. It was only after government intervention that the drug was again put on the market.

Roussel-UCLAF, a subsidiary of the pharmaceuticals giant Hoechst, declined to comment on the meeting with Willke. A spokesman said that RU-486 is only a new alternative to surgery and its withdrawal would have no effect on the number of abortions carried out. In Washington, the National Right to Life Coalition also declined to comment on possible boycott action while Willke is still in Europe.

Right to Life is one of the most vocal and powerful minority lobbies in the United States, capable of assembling thousands of people at rallies to protest against abortion. Any decision to boycott Hoechst products would therefore be taken seriously by the company, even though it has no plans to introduce RU-486 in the United States.

Although it is illegal for federal laboratories to carry out research on abortifacients, the potential contraceptive properties of RU-486 are being studied. At low doses, the drug is thought to impair the implantation of a fertilized ovum in the uterus lining. Since implantation is a criterion for pregnancy, such a function would technically be 'contraceptive' and not 'abortifacient'.

There is no national legislation on abortion in the United States; only a Supreme Court ruling makes it illegal for states to outlaw abortion. But a test case currently before the Supreme Court has challenged this ruling. The judgement, which could come in the next month, will stir emotions in the anti-abortion lobby, whatever the outcome. **Peter Coles**

# Hope for nuclear industry?

## Boston

THE US Nuclear Regulatory Commission (NRC) is expected soon to authorize sweeping regulatory changes that will shorten the licensing procedure for nuclear plants. The new procedure eliminates the requirement for a separate operating licence for newly constructed reactors, thereby limiting the opportunity for public intervention once a plant has been built. The five-member nuclear commission is expected to vote on the licensing overhaul as early as this week, and the measure is said to be almost sure to win approval.

Renewed interest in nuclear power and frustration over the experiences at the Shoreham and Seabrook plants —

## INTERNATIONAL SCIENCE

# Non-aligned line-up for new technology

## New Delhi

A centre for science and technology of non-aligned and other developing countries was formally established in New Delhi last week after 31 countries signed the centre's statute. Joint research programmes and exchange of experts are some of its objectives, but the centre primarily seeks to pool existing scientific resources, technological and consultancy capabilities in member countries for their common benefit. The centre will be financed by contributions from each member country, fixed at \$15,000 per year. The initial 31 countries are from the Indian subcontinent, Africa and Eastern Europe, but China is not a member. As the host, India has offered an extra \$1.1 million for office building, equipment and transportation. The first-year budget of the centre is \$1.6 million. It will have an Indian director but other key posts are to be filled by people from other member countries.

Computer software, biotechnology, renewable sources of energy telecommunications and new materials are among the areas from which about 30 specific collaborative programmes have been identified. Project expenses will be met by participating countries; the centre will play only a catalytic and coordinating role, although there will be money for pilot plants or infrastructure development.

The centre's first task is to prepare a directory of science and technology institutions, and a list of transferable technologies already available in member states. There are proposals for a common gene bank, a shared database on science and technology and a consortium for technology promotion within the non-aligned club.

K.S. Jayaraman

both now built but not operating — have propelled consideration of the new rules. Proponents of the changes argue that the current licensing procedures are unnecessarily cumbersome and expensive to follow.

If adopted, supporters say the new rules will shorten the time needed to begin operating a new plant, simplify the site-selection process and bring standardization in reactor design. In addition, advocates believe that the changes would be an important symbolic incentive to the nuclear industry and to poten-

ess. The new rules would not affect any existing plants (licensed or otherwise).

The idea of revising the licensing procedure for nuclear power plants has been considered for several years, but has usually been discussed as a matter to be dealt with by Congress. Although members of the nuclear regulatory commission and the nuclear industry have urged Congressional action to simplify the licensing procedure, Congress has so far failed to take up the matter. According to one inside observer, the commission "finally got fed up with Congress and decided to go out and change the licensing procedure on their own".

But Ken Bossong, director of the Crit-

The way things were: work in progress on the Palo Verde nuclear generating station

tial financial backers of nuclear power.

But critics argue that the proposed changes are illegal and unsound, and that they are a "blatant effort" to limit public involvement in the licensing process. If passed, the rule changes are sure to face a legal challenge. According to several sources, anti-nuclear groups are meeting currently to decide "who will take the lead" in the legal challenge.

Under the proposed licensing process, only one licence will be given by the nuclear regulatory commission at the construction phase of a new nuclear reactor which would be a combined "construction and provisional operation" licence. At some point shortly before construction of a plant was complete, the utility would seek approval to 'implement' its operating licence.

In other changes would allow utilities to obtain "early site permits" up to 20 years before building a plant. Public disputes over the suitability of the location for the reactor would have to be settled at this early stage. The nuclear regulatory commission would also "pre-approve" several standardized nuclear reactor designs. By using one of these designs, utility would be exempt from part of the present public review proc-

ical Mass Energy Project, likens the proposed changes to awarding a university students a degrees "based only on their first year of school". He and other critics contend that the proposed changes "decrease if not eliminate" the possibility to consider flaws or fraud in the construction process, or changes in the site situation — such as roadways, population changes, hospitals or schools — that may occur during the 20 year period after the site has been approved.

In addition, Bossong and others say that the new rules preclude evaluating the financial ability of the utility to operate the plant once construction is finished. Despite the controversy already raging around the rule changes, there is little certainty over how they might affect the beleaguered nuclear industry.

Although they ought to make the construction and licensing process simpler and more concise, several observers note that the financial community is greeting the proposed changes warily. As Bossong puts it, "the industry still has to grapple with widespread public opposition to nuclear power, lack of nuclear waste facilities and economics that are not competitive with other sources of energy".

**Seth Shulman**

## GREEN POLITICS

# New pragmatism pays off

## Munich

THE Greens are on the rise again in West Germany. For the first time in two years, a *Land* (state) government including the Green party was formed in West Berlin on 16 March, pointing the way towards more Green political power. Ten days earlier, national party members elected an executive committee (*Vorstand*) intent on forming a coalition with the Social Democrats (SPD) in the *Bundestag* after the 1990 election. The possibility of an SPD/Green coalition is stronger than ever in the aftermath of heavy losses for the conservative Christian Democratic Union (CDU) in recent elections.

Even as their political fortunes are waxing, the Greens are taking a less utopian view toward ridding society of what they see as its technological evils. A survey of Green politicians in Bonn and elsewhere reveals a more pragmatic attitude towards divisive issues such as genetic engineering, nuclear research and space exploration. Once advocates of banning everything to do with technology, ten years of political experience has tempered Green extremism.

The Greens shared power once before in a stormy coalition with the SPD in the *Land* of Hesse from 1985 to 1987. But a conservative coalition led by the CDU took over, in part because of governmental paralysis on nuclear issues. They faded from view after that, plagued by internal struggles. The election of a pragmatic leadership at the Green party conference in early March reveals the new direction of the party. The three executive committee spokespersons elected—Verena Krieger of Witten, Ruth Hammerbacher of Osnabrück and Ralf Fücks of Bremen—were careful to avoid the kind of name-calling that was so destructive two years ago. The election, and the

decision of West Berlin's Greens to form a coalition with the SPD, reflects the wishes of Green voters to see their leaders take action, even if it means compromise.

Because of its unique status, the Greens' success in West Berlin is hard to extrapolate to the rest of the country.

Small but steady progress of Greens.

The *Alternative Liste* (AL), a local Green party, had always been strong in some areas of West Berlin, which has a large population of draft-resisters and dropouts from society. After weeks of debate, the SPD and AL reached a compromise on governing the city.

But the results of community elections in Hesse on 12 March suggest that the Berlin result was not a fluke. Green support surged all over Hesse and helped topple a CDU government in West Germany's financial capital Frankfurt. A new political constellation seems to be forming which is widely seen as a threat to the re-election prospects of Helmut

Kohl's conservative coalition in 1990. According to a poll taken by the magazine *Spiegel* in February, Kohl's CDU and its Bavarian sister party CSU had reached a two-year low in popularity.

The compromise worked out between SPD and AL in West Berlin gives some clue as to what sort of science policy to expect in a national SPD/Green coalition. For example, the AL yielded on initial demands to stop construction of a nearly completed nuclear research reactor at the Hahn-Meitner Institute. Receiving a final licence for the reactor from the new environment senator, a member of the AL party, will be difficult, but the SPD is expected to ensure that it will be possible.

National Green politicians are quick to assure that they would not shut down research institutions. "It would be crazy to forbid nuclear physics research", says *Bundestag* member Otto Schily, "just because the atomic bomb is a danger to mankind". If the Greens come to power, says Schily, the freedom of research that is guaranteed in the West German constitution (*Grundgesetz*) "must not be touched". Schily belongs to the more 'realistic' wing of the Greens.

The most visible feature of the West German research scene that would be affected by Green involvement in government is space policy. West Germany's active collaboration in European Space Agency projects has been supported by a publicity-conscious government that seeks as much prestige as possible for its space programme.

Fücks criticized the space programme because of its ties to the military. Given all the ecological goals the Greens have in mind, it would be hard to continue to invest in expensive programmes such as manned space flight. Despite the criticism, it is unthinkable that a new West German government would renege on international contracts signed by its predecessors. Schily categorically excludes this possibility. The Greens still advocate a shutdown of all nuclear plants, and their views are not far from those of the general public in West Germany. Nearly 80 per cent of the population would prefer an immediate or gradual shutdown, according to the *Spiegel* survey.

Like nuclear power, genetic engineering is an issue that calls for sweeping condemnations from Green politicians. But the current leaders have begun to break from their predecessors in admitting some practical uses for molecular biology, such as the development of AIDS treatments.

Maintaining their political momentum going into the long series of *Land* elections in 1990, culminated by the *Bundestag* election, will be difficult. But recent events have ensured that the Greens will not just go away. **Steven Dickman**

## ENVIRONMENTAL PROTECTION

## Compromise reached on toxic waste

### Paris

DELEGATES from 116 nations meeting last week in Basel, Switzerland, under the aegis of the United Nations Environment Programme, failed to reach unanimous agreement on rules governing dumping of toxic waste. Only 34 nations signed a treaty, which had taken 18 months to draft, but 105 did sign a final compromise document. The United States, Britain and the Soviet Union were among those calling for more discussion before signing a treaty.

Some developing nations wanted a total ban on the export of toxic waste because, they argue, they are easy prey for industrial companies seeking to dispose of waste away from their own back yard. But for most European and other industrialized nations, waste disposal is an acceptable

commercial enterprise and a ban would be out of the question.

The Organisation for African Unity sought powers to search ships in coastal waters for clandestine cargoes of hazardous substances, but this is against international maritime law. As a compromise, the summit drafted an agreement by which signatories undertake to export waste only to countries having sufficient facilities and expertise to deal with it and only following written confirmation by both the exporter and the importer. Signatories also agree to reimport waste rejected by another country, but they will not be obliged to accept responsibility for accidents arising from waste dumped before the new regulations come into force.

## Distinguishing fraud from error

SIR—There is a danger in the controversy over fraud in science of merging the concepts of fraud and error. The call for an audit of scientific papers for error is a symptom of this trend. Fraud such as fabricating data or publishing the work of others as one's own is of course serious, particularly when it involves assessment of drugs and other medical treatments where lives are at stake. But error is an inevitable part of science. This fundamental point is being missed in the current debate. Scientists struggle to express their ideas, struggle with recalcitrant organisms, use advanced laboratory techniques that they barely understand, and study systems so complex that many hypotheses may seem to fit the data. This is not the orderly process that some imagine science to be. One does not go into a laboratory and order a cure for heart disease and get a guaranteed result. Results in science are never guaranteed and are never free from error. Newton, Einstein and Darwin were all wrong in some respects, even though they are the standard by which we judge genius itself.

Science is a complex and subjective process, one man's enthusiastic promotion of an hypothesis may be another man's fraud. The history of science is full of individuals who turned out to be right but who, by the strict criteria proposed by some today, could be attacked for fraud. In the laboratory notebooks of Millikan's oil-drop experiments, it can be seen that he rejected many trials because his judgement told him that something was wrong. In today's climate he could be accused of blatant manipulation of the data, that is, fraud. The 'discoverer' of N-rays had bad technique and practised self-deception, but there was no fraud. Was Columbus guilty of scientific misconduct for his self-delusion about the circumference of the Earth? Kepler defended himself in his search for the "Music of the Spheres".

Some of the charges levelled in recently publicized cases include misclassification of control subjects, poor laboratory procedure (Benveniste) and complex issues of scientific method (Baltimore). These are real scientific issues, but not causes for hand-wringing and raised eyebrows, much less for congressional scrutiny.

Who ever said that when you open a journal you are reading a message carved in stone by some higher being? Every time one reads the scientific literature, it is necessary to be wary and to compare, test and evaluate methods, data and statistical methods. At no point do we have such a grasp on the truth, statistical, experimental or otherwise, that a panel can be certified as error hunters. Reviewers of a

paper are themselves often wrong (the original theory of continental drift was met by howls of laughter from 'respected' scientists). Who will review the error hunters? Who is qualified to punish whom?

So, is there error? Of course there is. But we should also note that every building built has flaws and half of them are ugly, every economic policy ever formulated is imperfect. We can only ask for perfection when the correct answer is known (for example, on the factory assembly line), but if the answer is known then it isn't science.

## Defence research

SIR—You report (*Nature* 336, 610; 1988) that the veterinary school at this university is being supported in a research project on the survival of bacterial pathogens in aerosols by the Ministry of Defence (MoD) Chemical Defence Establishment. The project is of evident relevance to biological warfare, if for no other reason than that proposals must have 'defence relevance' to qualify for MoD support. Whether or not the ministry's interests in biological warfare are legitimate, we believe that they are not appropriate to a veterinary school.

Unlike the research councils, MoD has no remit to improve animal health and welfare nor a broad peer-group-defined strategy. The medical and veterinary benefits of the Bristol project are merely a spin-off of its defence interests.

While research support by the research councils appears to be increasingly inadequate, MoD support of research in British universities and higher education establishments has increased by 60 per cent since 1984-85 (from £10 million to £16 million). Consequently there is a danger that scientists are relying increasingly, as at Bristol, on support from government or from commercial organizations with narrow research objectives and a strong interest in confidentiality, even secrecy. We believe that such support undermines the integrity and openness with which research can be conducted.

Clearly, the freedom with which a project is formulated is compromised when it has to conform to concerns of a sponsor (for example, defence or financial profit) that are completely irrelevant to the purpose of the research (for example, the improved health of livestock). The freedom to publish is not adequate safeguard of independence when the freedom to propose is restricted.

We urge research institutions and individuals to take a long hard look at the way in which the motives of funding bodies

may subtly redirect and compromise research priorities and independence.

## Imperial Japan

SIR—We should like to comment on the article (*Nature* 337, 107; 1989) in which Japan's deceased Emperor Hirohito was described as an admirable biologist. We fear that the article may be abused by those who wish to enhance or maintain the emperor system, and that it is likely to be cited in sentences such as 'A leading scientific journal, *Nature*, also admires the Emperor as a prominent biologist'.

Since Hirohito died on 7 January, programmes on television and articles in newspapers and magazines have been full of admiration and glorification for the personal qualities of the emperor. Neither the mass media nor leading intellectuals have touched on the dangerous and inadequate aspects of the emperor system, which have been used to control the ideology and attitude of Japanese citizens. Opinions against the emperor or the emperor system are suppressed by both direct and indirect pressure.

There are some problems in associating biology with the emperor. First, the words 'naturalist' or 'biologist' give a relatively good impression, and have been used to make an admirable personality of the emperor. Second, there are few faculty positions and departments in the fields of fundamental biology (except biotechnology and molecular biology) and funds are also scarce in Japan. But biologists can get money for international meetings, and other scientific activities in subjects related to those in which the emperor was interested. So some biologists have tended to use the emperor to get funds, while the government and conservative intellectuals have used such biologists and their activities to enhance the respectable image of the emperor. The International Biological Prize (established to celebrate the sixtieth year of the emperor's reign) is also used to enhance the image of Japan's emperor in the eyes of other countries.

# Rise and fall of Western diseases

David J. P. Barker

Nutrition and hygiene during early childhood are important in determining the risk of the diseases which follow industrialization. We still know little about the processes involved.

THE term 'Western diseases' is used to describe a group of diseases common in industrialized countries but uncommon elsewhere<sup>1</sup>. These diseases are regarded as a consequence of the environmental changes accompanying industrialization and prosperity; it is often argued that their prevention depends on a return to practices of the past — for example, resumption of a diet high in complex carbohydrates and low in animal fats.

'Western' characterizes only the international distribution of diseases. It does not describe other features of disease distribution in populations. In particular, it does not predict changes in incidence other than the rise with the beginnings of industrialization.

Two main environmental changes during industrialization are in hygiene and in diet. Improvements in sanitation and housing lead to falls in mortality from infective diseases, especially among children<sup>2</sup>. Increased intake of total calories, animal fat, fruit and fresh vegetables, vitamins and minerals leads to better growth and development of children and contributes to the decline of infective diseases such as tuberculosis.

Epidemiological findings suggest that many diseases in industrialized countries fall into one of three groups, which can be shown by data from England and Wales, where numbers and causes of all deaths have been recorded for 140 years. The first group, associated with affluence, includes gallstones, renal stones and cancers of the breast, ovary and prostate. The incidence of these diseases has risen steeply during this century, particularly in more prosperous areas. The second group, associated with poor living standards, includes chronic bronchitis, stroke, stomach cancer and rheumatic heart disease. The incidence of these diseases has fallen during the past 50 years as living standards have improved. These diseases are commonest in the least affluent areas and in people with the lowest incomes. The third group is at different times associated with both affluence and poverty, and includes ischaemic heart disease, appendicitis and duodenal ulcer. The incidence of these diseases rose in the early part of this century, when they were more common among the rich. Subsequently the incidence fell and they are now commoner among poorer people.

The annual death rates from this last group of diseases in England and Wales<sup>3</sup>

are shown in Fig. 1. Together with those in the first group, they can be termed 'Western' diseases. Why have they declined when the environmental changes of industrialization have persisted?

Poliomyelitis was rare in Britain before this century but, as in other countries, it began to appear as hygienic and general living standards improved. This is in contrast to all the other common infective diseases, which were declining at this time. There was a sharp rise in notifications of poliomyelitis after the Second World War which persisted until the introduction of large-scale immunization (Fig. 1). It is now known that the rise of poliomyelitis resulted from the increasing vulnerability of the central nervous system to poliovirus infection with increasing age. As hygiene, sanitation and housing improved, the proportion of children escaping infection during the relatively safe period of infancy rose, and the number of cases of paralytic disease at later ages therefore rose in parallel.

The outbreaks of appendicitis which have accompanied industrialization in many parts of the world can similarly be explained as an age-dependent consequence of infection<sup>4</sup>. In England and Wales, death rates from appendicitis increased abruptly and steeply from around 1900, and then fell progressively from the 1930s onwards (Fig. 1). There is strong evidence that this trend reflects

changes in incidence of the disease, and similar trends were recorded in other European countries and in the United States. The explanation of these trends is thought to lie in the reduced levels of enteric infection in young children brought about by better hygiene, making them liable to develop appendicitis in response to infections at a later age. With continued improvements in hygiene, exposure to infection throughout childhood and early adult life became more uncommon. Because the appendix seems to be less vulnerable to infection after about 30 years of age, appendicitis declined.

Death rates from duodenal and stomach ulcers rose and fell in a similar way. The distribution of duodenal ulcer with social class was similar to appendicitis; while it was increasing it was more common among the rich, but as it declined it became commoner in poorer people. Recent findings of *Campylobacter*-like organisms in peptic ulcers suggest that the disease is spread by an infective agent<sup>5</sup>. The time trends point to age-dependent consequences of infection.

The trends in deaths from thyrotoxicosis (Fig. 1) show another process by which a rise in disease can be followed by a fall. Death rates rose to a peak in the 1930s and thereafter declined. Most deaths from this disease occur in the elderly, among whom toxic multinodular goitre is the usual cause of thyrotoxicosis. Analyses

FIG. 1 Average annual mortality from selected diseases in England and Wales from 1901, and numbers of notifications of poliomyelitis in five-year periods<sup>3</sup>.

of age-specific rates in successive generations<sup>6</sup> show that rates rose progressively in people born after 1836 and reached a peak in those born between 1871 and 1886. This is shown in Fig. 2, which gives rates in each generation according to their year of birth.

Figure 2 also shows the progressive increase in dietary iodine in Britain during this century, as a consequence of diversification of diet and availability of iodine in many foods including fish, meat and milk<sup>7</sup>. Iodine deficiency during childhood was widespread among people born in Britain in the 1800s. Successive generations, however, were exposed to more iodine in adult life. There is evidence that people who are iodine deficient in youth are less able to adapt to increased iodine intake in later life and tend to develop thyrotoxicosis<sup>8</sup>. This would explain the rise in deaths from thyrotoxicosis in the early part of this century (Fig. 1). Successive generations born after 1880 were exposed to more iodine in childhood, which would have lessened their susceptibility to iodine in adult life; accordingly, thyrotoxicosis mortality fell from around 1940 (Fig. 1). This explanation of the time trends accounts for the apparent paradox that toxic nodular goitre is now common only in those areas of Britain where iodine deficiency used to be prevalent.

The essential process thought to underlie the trends of occurrence of toxic nodular goitre is a response to an environmental influence during early life, which has a critical effect on the ability to adapt to subsequent exposure. The same process may determine trends in ischaemic heart disease. Death from ischaemic heart disease was not distinguished from that from other forms of heart disease before 1940, but other evidence reveals a steep rise in rates during the first part of the century. From 1940, death rates continued to rise progressively and reached a plateau in the 1970s (Fig. 1). Since 1980 there has been a small decline. Similar patterns occurred in the United States, Canada, Australia and New Zealand; initial rises were followed by substantial falls, of around one-quarter in the past 30 years in the United States<sup>9</sup>.

Although death from ischaemic heart disease was more common in wealthier people during its steep increase in Britain, it is now more common in less affluent areas and among people with lower incomes. This geographical distribution is the reverse of that for other diseases thought to be caused by the Western diet — gallstones, renal stones and breast cancer are all more common in more prosperous areas. The geographical distribution of ischaemic heart disease is closely related to that of poor child health and development, indicated by high infant and child mortality about 70 years ago<sup>10</sup>. The aetiology of this disease may therefore

FIG. 2 Relative mortality from thyrotoxicosis in successive generations of women in England and Wales according to year of birth, together with estimated per capita daily iodine intake from milk, meat and fish<sup>7</sup>.

depend on two groups of environmental causes: one associated with affluence and likely to be mediated through a high-energy, high-fat diet; the other acting during childhood and associated with poor living standards. The rise in the disease results from an increase in the first, its fall from reduction in the second.

Further evidence of the effect of this second group of environmental causes is the inverse relation between risk of ischaemic heart disease and height, which is largely determined by growth in childhood. Long-term 'programming' of lipid metabolism during infancy, in response to infant feeding, is a mechanism for which there is increasing evidence in experimental animals and which could be a link between childhood and ischaemic heart disease. Another link may be the known inverse relation between fetal growth and blood pressure in adult life<sup>11</sup>.

Each of the diseases shown in Fig. 1 may rise and then fall in response to one environmental change that accompanies industrialization. Such diseases characterize the change from a mainly rural to a mainly industrial society. Responses to the childhood environment, including age-dependent consequences of infection and adaptation to diet during early life, may be important causative factors.

The search for causes of 'Western' diseases has concentrated on the adult environment. The importance of the childhood environment in determining responses throughout life may have been underestimated. Models of disease based on the effects of cigarette smoking, an influence in the adult environment which has been intensively studied, may have limited general application. Where differences in individuals' susceptibility to disease cannot be explained by differences in the adult environment, as is the case for ischaemic heart disease, they have often been attributed to genetic causes — especially if the disease has a familial tendency. Part of what is now regarded as the genetic contribution to ischaemic

heart disease may turn out to be the effect of the intra-uterine or early postnatal environment.

Critical adaptations during early life may determine optimal rates of change within populations. Appendicitis and duodenal ulcer became common at an early stage of improvements in hygiene. The size of epidemics of these diseases may depend on the speed with which hygiene improves throughout the population. The rise of appendicitis in Britain can be linked to the introduction of domestic hot-water systems. The introduction of piped water supplies was spread over more than half a century, piped water not reaching some rural areas until after the Second World War. Swifter execution of public-health reforms begun in the nineteenth century might have reduced the incidence of this disease.

By contrast, critical responses to nutrition in childhood, such as those that occur in toxic nodular goitre and that are suspected in ischaemic heart disease, may limit the extent of dietary change that a generation can be exposed to without adverse effects. It follows that improvements in living standards during early industrialization should be directed at children. Although the industrial revolution in Britain brought high wages to adults, children continued to grow up undernourished, in large families, and in poor, overcrowded homes.

Steep increases in the incidence of 'Western' diseases regularly follow industrialization in the developing world. Among people of Chinese origin, improvements in hygiene may occur without changes in the traditional diet. Elsewhere, as in the slums of many cities in the developing world, diet changes but poor hygiene persists. If more was known about the processes by which the environment in early life influences adult health, the hygienic and nutritional benefits which will accompany industrial development might be maximized, and the rise in incidence of 'Western' disease minimized. □

# Heat conduction is a can of worms

Heat conduction is usually regarded as a phenomenon in which energy diffuses away from regions of high temperature, but diffusion may not always be a sufficient explanation.

WHETHER it is pleasing or otherwise to be told that a familiar principle is also a pack of lies is a matter of temperament. Some people are natural iconoclasts, others wish that at least some of the basic verities were eternal. But there are good reasons why what is known as Fourier's law (of heat conduction), which many people are still taught at high school, should be regarded as the crudest approximation to the truth. The interesting, but perplexing, question is that of what should take its place.

Most simply put, Fourier's law relates the flux of heat at any point in, say, a one-dimensional solid such as a metal bar to the temperature gradient at that same point. The heat flux and temperature gradients are taken as proportional to each other, with a constant of proportionality called thermal conductivity and with a minus sign (to allow that heat flows against the temperature gradient). The relationship is that of the diffusion equation, describing the diffusion of a chemical in a liquid.

High-school problem-solvers know how this can be used to calculate the change of temperature with time at any point in, say, a conducting bar. The rate of change with time of the temperature at any point, determined by the rate at which energy accumulates there, is evidently proportional to the rate of change with distance of the heat flux, with a constant which is the reciprocal of the specific heat and with another minus sign. The outcome is an equation relating the first time-derivative of the temperature and the second distance-derivative of the temperature. Given the distribution of temperature at the outset, it is then possible to calculate the temperature everywhere at all later times.

One might, for example, start with a metal bar at room temperature for half its length and at some higher temperature for the other half and follow the approach to equilibrium, when the temperature along the bar will be everywhere the same. But there is one obvious respect in which this result flies in the face of common sense: all solutions of these equations entail that the temperature everywhere along the bar will begin to change from the outset, however long the bar.

The implication is that the influence of the hotter half of the bar propagates instantaneously even to the most distant parts of the cooler half, which is unphysical. It is not merely that relativity disallows influences propagating faster than the speed of light, but that heat must get

from one end of the bar to the other by some physical process plainly overlooked by Fourier's law.

This is the starting point for a review earlier this year by D. D. Joseph of the University of Minnesota and Luigi Preziosi of the University of Naples (*Rev. Mod. Phys.* **61**, 41; 1989). Their objective is to define the circumstances in which heat can be propagated by means of waves, which has been observed in liquid helium and in some dielectric crystals at low temperatures. But their review inevitably begins with a discussion of the mechanisms of heat conduction and turns out to be a stimulating history of attempts to improve on Fourier's law, with the loose ends left dangling for all to see.

That there should be loose ends is not surprising; the mechanisms of heat transport are many and different. In a gas, energy is physically carried by molecules and transferred whenever they collide. In solids, on the other hand, lattice vibrations are a universal means of heat transport, but free electrons also play an important part in metals.

In all cases, the physical transport of heat from one place to another requires that some physical interaction should release energy at the destination — in a gas, the collision of an energetic molecule or, in a solid, the conversion of a quantum of energy in one vibrational mode into one or more quanta tied to other modes (which is possible only because of the anharmonicity of the vibrations of real crystals). Improvements on Fourier's law must take account of these processes, which involve microscopic energy conversion with characteristic times and distances (the time between collisions and the mean free path in a gas, for example).

Nobody will be surprised that James Clerk Maxwell is credited with the first important contribution to the argument, in 1867 (*Phil. Trans. Roy. Soc. Lond.* **157**, 49; 1867). Following logic and his instincts, Maxwell (working with his kinetic theory) concluded that the spatial gradient of temperature is not simply related to the heat flux, but to a combination of that and a quantity proportional to the time-rate of change of the heat flux. The constant of proportionality must evidently have the dimensions of time; numerically, it is a 'relaxation time' related (in Maxwell's case) to the interval between molecular collisions.

Joseph and Preziosi observe that Max-

well, having arrived at this conclusion, promptly discarded the extra term he had imported into the equation of Fourier's law on the grounds that the relaxation time must be negligible. In the event, his equation was rediscovered only in 1948, by C. Cattaneo. Mathematically, Fourier's law in its simple form boils down to a differential equation for the temperature (as a function of position and time) which is strictly equivalent to the diffusion equation (which is why the ratio of the thermal conductivity and the specific heat of a material is called its thermal diffusivity). Maxwell's formulation, and that of Cattaneo, are by contrast equivalent to the partial differential equation known as the 'telegraph equation', which is itself a modification of the more familiar wave equation and whose solutions are waves which are attenuated as they propagate. So why do we not more often encounter phenomena in which heat seems to propagate as waves, not by diffusion?

As early as 1917, Nernst was arguing intuitively that, at low temperature, propagating heat should have inertia of a kind; a pulse of internal energy arriving at some point in one direction might be expected to continue in the same direction in the absence of the influences that, at high temperature, would randomize the internal motions. That, said Nernst, should make wave propagation possible. In 1941, Landau developed the two-fluid theory of liquid helium II and predicted the existence of heat waves, recognizable as temperature oscillations, which he called 'second sound'. The prediction was confirmed in 1944, when Peshkov measured the speed of second sound in helium II. Peshkov also predicted wave-like heat propagation in low-temperature crystals, also now confirmed.

So why not room-temperature heat waves? Joseph and Preziosi take the view that the question cannot be decided until more is understood about the spread of relaxation times in the process of heat conduction. Meanwhile, they advocate a further modification of the equation corresponding to Fourier's law to take account of these refinements. Luckily, as their history of the field shows, all kinds of new techniques — molecular dynamics, for example — are now being brought to bear on the issue. And, for practical purposes, Maxwell's guess that the simple form of Fourier's law suffices for most purposes remains valid.

# All for one, one for all, that is our device

Jon Seger

SOCIAL insects have played a unique role in the development of the theory of natural selection, ever since Darwin noted<sup>1</sup> that sterile workers pose a "special difficulty, which at first appeared to me insuperable, and actually fatal to my whole theory". Darwin saw in outline how selection might be "applied to the family, as well as to the individual", an idea that eventually gave rise to the modern theory of inclusive fitness<sup>2</sup>. Inclusive fitness is a general concept that applies to all situations in which relatives interact, but the motivation to develop it (and in particular, its connections with sex-ratio theory<sup>3,4</sup>) came largely from social insects. Theories of group selection<sup>5</sup> have also been inspired by insect sociality, and may soon receive new impetus from the same source.

On page 420 of this issue<sup>6</sup>, Rissing and colleagues show that unrelated females of the desert leaf-cutting ant *Acromyrmex versicolor* seem to participate voluntarily in an unequal division of risk and labour during the establishment of new colonies.

Several different patterns of colony formation are found among social insects of the order Hymenoptera, and most have evolved more than once<sup>7</sup>. In some ants and bees, for example, a fraction of the parent colony's worker force departs with a newly produced female reproductive (gyne) who becomes the principal egg-layer (queen) of the resulting daughter colony. But in most social Hymenoptera, each gyne departs alone and attempts to establish a new nest and to raise a first

generation of workers without any help at all. In either case a colony has a single queen, and the relatedness of nestmates tends to be high.

The new colony may also be established by several or many gynes, without an initial worker force. This pattern is common among social wasps. Dominance hierarchies form among the cofoundresses, such that one or several high-ranking individuals monopolize reproduction, and subordinates act as workers. The average relatedness of nestmates varies widely, but cofoundresses seem to be significantly related in most species<sup>8</sup>.

Multiple foundresses also occur in some species of ants; by analogy to social wasps, one would expect them to be relatives. In 1910, the great myrmecologist William Morton Wheeler<sup>9</sup> assumed "without doubt" that two cofounding females "were sisters that had accidentally met . . . and had renewed the friendly relations in which they had lived before taking their nuptial flight". Only in the past decade has it been learned that, in ants, cofoundresses are usually unrelated. The first evidence came from behavioural studies showing that gynes readily team up with each other independent of the distance between their natal colonies (and thus presumably independent of their relatedness)<sup>10,11</sup>. Recent genetic studies of relatedness within colonies of *Solenopsis invicta*<sup>12</sup>, *Veromessor pergandei*<sup>13</sup> and *A. versicolor*<sup>13</sup> show that cofoundresses are indeed no more closely related than random individuals drawn from the population at large.

In the laboratory, gynes have survived better in groups than alone<sup>10</sup>, and foundress groups of moderate size have produced more first-generation workers, more quickly, than have smaller or larger groups<sup>10,11</sup>. Species that frequently found nests cooperatively often engage in reciprocal brood raiding, with small colonies tending to be eliminated by their larger neighbours<sup>10,11</sup>. Thus at high population densities, cooperative founding may greatly increase the probability that a given nest will survive long enough to produce reproductives.

An alliance may improve survival, but given survival, it dilutes the expected reproductive success of each foundress. Conflict between foundresses or between workers and foundresses often begins soon after the emergence of the first workers<sup>10,11,14</sup>, and such conflict often leads to the expulsion or killing of one or more foundresses; in many species with multiple foundresses this process goes to completion and the mature colony is monogynous<sup>11</sup>.

In most ant species, foundresses raise the first workers on secretions derived metabolically from flight muscle and fat<sup>7</sup>, and they never leave the nest. *A. versicolor* is unusual in that one found-

## Life imitates (experimental) art

D. K. Bailey

THE white globules in this micrograph are chilled droplets of a carbonate melt, set in a groundmass of carbonate-rich volcanic ash. There has been much controversy as to whether such 'carbonatite' magma can form directly by partial melting of the mantle, or whether a two-stage process, involving modification of a mantle melt at shallower, crustal levels, is required. Recently, Margaret Wallace and David Green (*Nature* 335, 343–346; 1988; see also the accompanying News and Views article by J. Gittins) reported the experimental formation of a carbonatite melt by melting a mantle peridotite composition at mantle pressures and temperatures, lending support to the idea that carbonatites can be primary melts from the mantle. Now Ken Bailey on page 415 of this issue reports the existence of a close natural analogue to this experimental melt — the droplets pictured above, from the Rufunsa volcanoes in Zambia. Although these carbonatites have been known for some time, the similarity of their composition to that produced in the experiments, together with the discovery by Bailey of inclusions of mantle-type chromium-rich spinel (such as the black diamond-shaped grain in the larger droplet) now provides evidence that they are the long-searched-for primary carbonate melts. Field of view is 3.4 mm wide.

ress forages outside the nest during the interval between nest establishment and the emergence of the first workers". Foraging is energetically costly and it exposes the forager to risk of predation. One might therefore expect the forager to be a subordinate foundress who was forced into the role by her dominant nestmates<sup>15</sup>, but Rissing and colleagues<sup>6</sup> find no evidence of conflict within foundress associations studied in the laboratory, either before or after emergence of the first workers.

Why should one foundress (the forager) perform such heroic service on behalf of nestmates to whom she is not related? The answer suggested by Rissing and colleagues is that efficiency matters above all else, in the race to establish a colony that survives the brood-raiding that will begin as soon as any neighbouring colony produces a worker force. Like her sedentary nestmates, the forager will have no chance to reproduce in the distant future if her colony succumbs early on. If the fates of cofoundresses are very tightly bound together then the appearance of selflessness may be only an illusion.

This argument seems to work best for the critical early history of the colony; it loses force as the colony matures and achieves greater security. When the time comes to produce reproductives, each queen would presumably wish the others gone. Rissing and colleagues observed 1.5 years of peaceful coexistence in their laboratory colonies<sup>6</sup>, which may well be a record for confounding ant species<sup>11</sup>. The story will become even more remarkable if this solidarity among unrelated queens remains unshaken throughout their lives. □

ONE of the central aims of topology is to classify all possible manifolds up to topological equivalence. A manifold is a multi-dimensional analogue of a surface, and two manifolds are topologically equivalent if one can be deformed continuously into the other. The time-honoured method for classifying manifolds is to construct topological invariants: computable numerical or algebraic data that are the same for topologically equivalent manifolds but that distinguish between topologically inequivalent ones. For example, the number of holes in an ordinary two-dimensional surface is such an invariant. S.V. Matveev and A.T. Fomenko (*Usp. mat. Nauk.* **43**, 5–22; 1988; *Russ. math. Surv.* **43**, 3–24; 1988) have now made several fundamental advances concerning one of the most unusual and surprising invariants, the volume of a hyperbolic manifold.

The usual notion of volume is changed if the object concerned is stretched or bent, but this particular version of volume is extraordinarily 'rigid', and is not changed by continuous deformations. In addition, Matveev and Fomenko disprove a conjecture of Thurston (*Bull. Am. math. Soc.* **6**, 357–381; 1982) about the hyperbolic three-dimensional manifold (3-manifold) of minimal volume. Moreover, their methods have unexpected connections with fundamental questions in dynamics.

Over the past century, almost all of the objectives in the programme of finding invariants for manifolds have been accomplished for cases in which the dimension is either two, or greater than or equal to four. The remaining case, that of 3-manifolds, has proved far more subtle and intractable. The most encouraging new direction is embodied in recent conjectures of Thurston to the effect that every 3-manifold can be cut into pieces, each of which has a natural geometric structure (see my News and Views article in *Nature* **328**, 16; 1987).

This conjecture is at first quite startling, because geometry involves rigid concepts such as lengths and angles, which are destroyed by topological transformations. But the result has long been known to be true (and languished, unappreciated) in two dimensions. For two-dimensional surfaces there are three fundamentally different kinds of geometry: euclidean geometry; elliptic geometry, in which no parallel lines exist; and, in many ways the most interesting, hyperbolic geometry, in which there are infinitely many distinct lines through a given point and parallel to a given line.

Elliptic and hyperbolic geometry are the two possible types of non-euclidean

geometry in two dimensions. Elliptic geometry can be realized on the surface of a sphere, which has constant positive curvature; and hyperbolic geometry is valid on a surface of constant negative curvature. Euclidean geometry comes in between: it holds for flat spaces, of zero curvature.

A surface without boundary, such as a sphere or multi-holed torus, can be equipped with a unique geometric structure. For example, as already mentioned, the sphere carries an elliptic geometric structure. The standard torus, with one hole, can be obtained by abstractly 'gluing'

Combinatorial data defining *a*, Thurston's conjectured minimal-volume 3-manifold; and *b*, the new record holder identified by Matveev and Fomenko.

together the edges of a square. Because the square is contained in a flat plane, and no distortion of distances or angles occurs when its edges are 'glued', the torus carries the same euclidean geometric structure as its parent square. It turns out that all other surfaces, that is, tori with two or more holes, can be equipped with a hyperbolic structure.

Except in the euclidean case, the geometric structure has a natural length scale. Two spheres, for example, differ only in their radius. If the curvature (the reciprocal of the radius) is normalized to 1, then the radius must be 1. This fixes the length scale. The area must then be  $4\pi$ ; and this number, so determined, is a topological invariant. Any surface, if it can be

#### THE GEOGRAPHICAL RESULTS OF MR. STANLEY'S EXPEDITION

It is evident from Mr. Stanley's stirring letters, which during the past week have cast all other topics into the shade, that pioneering in Africa is not yet at an end, and that the strange continent has not yielded up its vast wonder to knowledge.

Mr. Stanley's description of the character and extent of the Congo forest in his letter to Mr. Bruce is quite worth quoting:-

"Take a thick Scottish copse, dripping with rain; imagine this copse to be a mere undergrowth, nourished under the impenetrable shade of ancient trees, ranging from 100 to 180 feet high; briars and thorns abundant; lazy creeks meandering through the depths of the jungle, and sometimes a deep affluent of a great river. Imagine this forest

and jungle in all stages of decay and growth — old trees falling, leaning perilously over, fallen prostrate; ants and insects of all kinds, sizes, and colours murmuring around, monkeys and chimpanzees above, queer noises of birds and animals, crashes in the jungle as troops of elephants rush away; dwarfs with poisoned arrows securely hidden behind some buttress or in some dark recess; strong brown-bodied aborigines with terribly sharp spears, standing poised, still as dead stumps; rain pattering down on you every other day of the year; an impure atmosphere, with its dread consequences, fever and dysentery; gloom throughout the day, and darkness almost palpable throughout the night; and then, if you will imagine such a forest extending the entire distance from Plymouth to Peterhead, you will have a fair idea of some of the inconveniences endured by us from June 28 to December 5, 1887, and from June 1, 1888, to the present date, to continue again from the present date till about December 10, 1888, when I hope then to say a last farewell to the Congo forest."

From *Nature* 39, 560; 11 April 1889.

given a geometric structure of curvature 1, must have the same area  $4\pi$  as the sphere — and indeed in this case must be equivalent to a sphere. In a similar way negative curvature can be normalized to  $-1$ , and this also fixes a length scale. Therefore surfaces with a hyperbolic geometric structure also have uniquely defined areas.

For surfaces, far simpler invariants (such as the number of holes) achieve the desired classification, so this area has not featured prominently in most topologists' imaginations. But for 3-manifolds, analogously defined 'volumes' are turning out to be a much richer concept. As Thurston observed, there are eight distinct types of geometry in three dimensions. Three are euclidean, elliptic and hyperbolic geometry; the other five are harder to describe. Seven of these eight types of geometry are well understood, and so are the manifolds that carry such structures. The difficult case is that of hyperbolic manifolds: 3-manifolds that can be equipped with a geometry having constant negative curvature. For such manifolds one can normalize the curvature to  $-1$ , again obtaining a well-defined length scale; so the manifold has a uniquely determined volume. Moreover, this volume is a topological invariant — and a remarkably effective one.

Most invariants tend to be whole numbers. A simple example is the number of holes — clearly one cannot have half a hole. But the volume is a decimal. It is known that only a finite number of hyperbolic 3-manifolds have dimensions less than any given value. In particular there must be a smallest value. The corresponding manifold is presumably of some importance — otherwise why should it be the smallest one? So, which is it? Thurston conjectured that a particular manifold has

this smallest possible volume, and that its value is 0.98139.

Matveev and Fomenko use a new approach, combining two very distinct ideas: the complexity of a 3-manifold, and connections with dynamical systems. Complexity measures how complicated a combinatorial description of the manifold must be; the dynamical connection is described below. The complexity of a 3-manifold, which is a whole number, has many pleasant properties. For example, only finitely many manifolds have given complexity. The number of distinct 3-manifolds of complexity 0, 1, 2, 3, 4, 5 and 6 is precisely 3, 2, 4, 7, 14, 31 and 74, respectively. None of these is hyperbolic — in fact the first hyperbolic manifolds occur at complexity 9, and one of these is Thurston's conjectured manifold of minimal volume.

Using this notion of complexity, Matveev and Fomenko set up a computer algorithm to search for hyperbolic 3-manifolds and compute their volumes. They studied about a thousand manifolds in all. Among their list they found a new manifold, also of complexity 9, with the forbidding name  $(Q^2)_{8,2}$ , whose volume 0.94272 is smaller than that conjectured by Thurston. Indeed it is the only manifold in their list having smaller volume than Thurston's manifold, and they in turn conjecture that they have now found the true minimal volume. Because 3-manifolds involve 'curved space' they cannot be drawn directly, but their curious and intricate geometry may be gathered from two pictures (see the figure) showing the so-called singular graph for Thurston's manifold and the new, low-volume record holder. The singular graph determines certain combinatorial data from which the manifold can be constructed.

Matveev and Fomenko's very extensive

list of manifolds and volumes provides a wealth of valuable data against which to test conjectures. In particular their results cast doubt on one part of Thurston's programme for studying 3-manifolds. He suggests dissecting manifolds into simplexes (non-euclidean tetrahedra) and analysing how these fit together. But it now seems that some features of the mathematics depend on the manner in which this dissection is done, an unexpected difficulty.

Finally, there is a curious and deep connection with dynamics, which is central to Matveev and Fomenko's theory. Every hamiltonian dynamical system (that is, one in which there is no friction, so that energy is conserved) has associated with it a phase space determined by the position and velocity variables needed to specify its state. For example a mass moving in space requires three position coordinates and three velocity coordinates, and hence has a six-dimensional phase space. The subset of phase space corresponding to a fixed value of the energy is a manifold one dimension smaller — in this case 5.

For a simpler example, think of a simple harmonic oscillator (or idealized pendulum). This has one position coordinate and one velocity coordinate, giving a two-dimensional phase space. The constant-energy manifolds are concentric circles. But circles have positive curvature, hence elliptic geometry. Hyperbolic energy surfaces do not occur in two-dimensional phase spaces.

Matveev and Fomenko prove that something similar happens when there are two position coordinates and two velocity coordinates. The phase space then has dimension 4, and every constant-energy manifold has dimension 3. Thus a special class of 3-manifolds arises out of dynamics. Which? Under one further technical assumption, integrability, these manifolds can be characterized. They are precisely those 3-manifolds which can be cut into pieces, each having a geometric structure that is non-hyperbolic. Any of the other seven possible geometries may occur: hyperbolic geometry alone is forbidden.

Some of these ideas may sound outlandish, but they derive from long-standing themes in mainstream mathematics. What is new is the manner in which they have been brought together. Volume, a rigid geometric concept, now applies in a topological context; it is related to complexity; and hamiltonian dynamics somehow conspires to forbid even a tiny part of a constant-energy surface having constant negative curvature. The story is a remarkable and important affirmation of the power of the new geometric approaches to topology and dynamical systems. □

# Glycine maintains excitement

Alan C. Foster and John A. Kemp

THE explosion of interest in the NMDA (N-methyl-D-aspartate) receptor, one receptor subtype for the excitatory neurotransmitter L-glutamate, has generated several new concepts of transmitter function. Thus, it is now known that NMDA-receptor activation is conditional on a unique voltage-dependent regulation of channel conductance by magnesium<sup>1,2</sup>, and that the neuronal response consists of both short-term membrane conductance and long-term biochemical changes, the

concentrations of glycine increase the frequency of NMDA-receptor channel opening in a strychnine-insensitive manner, and suggested a mechanism involving allosteric regulation of the receptor complex through a distinct glycine binding site. This idea is supported by the existence of strychnine-insensitive <sup>3</sup>H-glycine-binding sites which have an anatomical distribution identical to that of the NMDA receptor<sup>3</sup>. It seems likely that the glycine-binding site is an integral

the onset of desensitization, but accelerates the recovery of the receptor from its desensitized state.

This is the first time such a mechanism for the regulation of a ligand-gated ion channel has been proposed; it may explain the large enhancement of NMDA responses achieved by glycine. If this were the sole mechanism through which glycine exerts its effects, then the co-agonist idea would be negated. But patch-clamp studies with the selective glycine antagonist 7-chlorokynureate, using a fast perfusion system similar to that of Mayer *et al.*, indicate that this compound can produce a complete block of NMDA responses<sup>11</sup>. Thus, glycine binding could have two effects, one involved with the initiation of NMDA-receptor activation and the other to speed up recovery from desensitization.

Many questions surround the role of glycine in the regulation of NMDA receptors *in vivo*. NMDA responses obtained in slices of adult central nervous system *in vitro* are generally not enhanced by glycine (or its analogue D-serine), but can be blocked in a glycine-reversible manner by glycine antagonists such as kynureate, 7-chlorokynureate and HA-966<sup>11-13</sup>. Thus, the facilitation of NMDA responses by glycine occurs in adult neurons, but under these experimental conditions extracellular glycine levels are sufficiently high to occupy all of the glycine-binding sites.

It has been suggested<sup>4</sup> that this situation may be the case *in vivo*, as levels of glycine in the cerebrospinal fluid are high (greater than one micromolar). Thompson *et al.*<sup>6</sup> report that glycine enhances NMDA responses in slices of cortex when applied in close proximity to the neuron under study in conditions of reduced perfusion, which are claimed to mimic more closely the situation *in vivo*. This agrees with recent studies *in vivo* which have shown a facilitation of NMDA responses by locally applied glycine or D-serine<sup>14-16</sup>.

Thompson *et al.* also demonstrate a

latter caused by elevated intracellular calcium concentrations<sup>1</sup>. Furthermore, receptor activation involves not only the binding of an agonist, such as L-glutamate or NMDA, but also an allosteric facilitation by glycine binding to a separate site within the receptor complex<sup>1</sup>. Two papers in this issue provide further insights into this effect of glycine. On page 425, Mayer *et al.*<sup>5</sup> present evidence that at least part of the enhancement of NMDA responses by glycine occurs through a previously unknown mechanism — an acceleration of recovery from desensitization. And on page 422, Thompson *et al.*<sup>6</sup> demonstrate that glycine facilitates NMDA receptor-mediated neuronal excitation in slices of cerebral cortex, suggesting that glycine is involved in the tonic regulation of transmission.

The effects of glycine on the NMDA receptor are distinct from its long-established role as an inhibitory neurotransmitter in lower brain areas and spinal cord, mediated by a strychnine-sensitive chloride conductance. Johnson and Ascher<sup>7</sup> have shown that submicromolar

part of the receptor complex, because glycine facilitation is maintained in isolated membrane patches<sup>1</sup> following solubilization of NMDA receptors<sup>8</sup>, and in NMDA receptors expressed in *Xenopus* oocytes following injection of rat brain messenger RNA<sup>9</sup>. The effects of glycine on the NMDA receptor have been compared with those of benzodiazepines on the GABA<sub>A</sub> receptor, but the magnitude of the enhancement of NMDA responses by glycine is much greater than that seen with benzodiazepines on GABA responses. Indeed, Kleckner and Dingledine<sup>10</sup> claim that no NMDA-receptor response can be obtained in the absence of glycine, and propose that receptor activation requires the binding of both glycine and L-glutamate as 'co-agonists'.

The new findings of Mayer *et al.*<sup>5</sup> are of direct relevance to this problem and add a new facet to the glycine story. They suggest that the main effect of glycine is to prevent desensitization, a decline in the receptor response which occurs during a prolonged agonist application of the NMDA receptor. Glycine does not block

facilitation of synaptic responses by glycine. This was observed only in the fraction of synaptic responses which exhibited an NMDA receptor-mediated component under these experimental conditions. This effect of glycine is likely to be a widespread phenomenon, as similar observations have been made in hippocampal neurons in culture<sup>17</sup> and in thalamic neurons *in vivo*<sup>18</sup>; and can be inferred at various synapses in the central nervous system from earlier studies using HA-966<sup>18,19</sup> which is now known to be a selective glycine antagonist<sup>13</sup>. Thus, glycine facilitation of synaptic responses mediated by NMDA receptors may be a common regulatory mechanism at excitatory synapses.

Clearly, it is now of interest to define the processes that regulate extracellular glycine concentrations in regions of the brain where NMDA receptors play important roles. Alterations of these systems would lead to profound changes in

neuronal activity mediated by NMDA receptors (see figure). The possibility that endogenous glycine antagonists (such as kynurenate) may be involved in regulating neuronal function should also be considered. If the main facilitatory effect of glycine is to accelerate recovery from desensitization of the NMDA receptor, it is likely that glycine will act in physiological situations where prolonged responses are required and repeated activation is necessary, such as induction of long-term potentiation. Conversely, a pathological excess of glycine could lead to prolonged excitation and epileptiform activity, contributing to the overactivation of NMDA receptors suspected to occur in seizure disorders and neurodegenerative disease. □

## EXTREME ULTRAVIOLET ASTRONOMY

# A new window on the Universe

*P. Gondhalekar and C. Jordan*

THERE are few spectral ranges in which observations of astrophysical sources have not been made. One of the few is the extreme ultraviolet region, which is virtually unexplored owing to earlier assumptions that the interstellar medium would be opaque at wavelengths between the hydrogen Lyman photoionization edge (91.2 nm) and about 30 nm. But during the past decade there has been increasing evidence that the absorbing interstellar material is not uniformly distributed. The growing optimism concerning the possibility of detecting this unexplored radiation from various sources was reflected at a recent meeting\*. It became clear that observations in the extreme ultraviolet could provide crucial tests of current theories concerning objects as diverse as active galactic nuclei, cool dwarf stars and the jovian aurora. The growing confidence in, and enthusiasm for, the new astronomy was amply demonstrated by the presentation of many plans for suitable telescopes for future space missions.

The turning point for extreme-ultraviolet astronomy came in 1975 with the detection of emission from the white dwarf HZ43, by an instrument on the Apollo-Soyuz mission. More recently, several nearby hot white dwarfs were observed with the Voyager ultraviolet spectrometers (J.B. Holberg, University of Arizona). Soft X-ray spectra of some sources, including cool stars in the proximity of the Sun, were obtained with the X-ray satellite, EXOSAT (N.E. White,

ESTEC) which was sensitive to wavelengths up to about 40 nm.

Also, the case for observing Solar System objects in the extreme ultraviolet has already been established by spectra of the giant planets and their satellites, obtained from Voyager 1 and 2. For example, strong lines of oxygen and sulphur ions are observed from the Io plasma torus. Improved spectra extending to wavelengths below 60 nm should allow an improved understanding of the plasma processes causing the jovian auroral emission as ions precipitate from the magnetosphere (P.D. Feldman, Johns Hopkins University; W.M. Harris and J.T. Clarke, University of Michigan; S. Chakrabarti, University of California, Berkeley).

The local interstellar medium is of great interest because the distribution and density of the local gas determines the direction and distance to which extreme ultraviolet sources can be detected. The most accurate neutral-hydrogen column densities come from measurements of ultraviolet absorption in spectra of discrete stellar sources, but these do not give sufficient spatial coverage to establish the global distribution. All-sky surveys at 21 cm, the principal hydrogen radiowave emission line, do give full coverage but the spatial resolution is too coarse to measure the hydrogen opacity in a particular direction. (C. Heiles, University of California, Berkeley; D. York and P. Frisch, University of Chicago).

There is a diffuse, hot (10<sup>6</sup> K) component of the interstellar medium which is an important source for ionizing helium, but

its location and how pervasive it is are questions still much debated (F. Bruhweiler and K.-P. Cheng, Catholic University; P. Jackobsen, ESA). The overall picture that is emerging is that the local region is relatively highly ionized and thus has low opacity, rather than being devoid of material; there are higher neutral-hydrogen mass column densities at larger distances in the galactic plane, particularly towards the Galactic Centre. Large molecular-cloud complexes, such as those in Taurus and Auriga, add regions of high absorption but there are galactic longitudes (around 230°) where absorption is lower than average.

It seems unlikely that any small 'windows' exist through which extra-galactic sources might be viewed at the longer wavelengths (Heiles), but there is a good chance that active galactic nuclei and quasars could be observed up to wavelengths of 20 nm (H. Marshall, University of California, Berkeley). The general advice for observing to great distances is to observe out of the galactic plane, as the colder, more dense medium has a smaller scale height. There is sufficient uncertainty in the distribution of the hot and cold components however, to guarantee that extreme-ultraviolet surveys will add considerably to our knowledge and understanding of the interstellar medium.

There is little doubt that the local interstellar medium will be transparent to extreme-ultraviolet radiation from many types of stars. Existing observations of X-ray emission from main-sequence B (hot, blue-white) stars lead to models which predict the presence of two component, wind-driven shocks with temperatures in the range 10<sup>5</sup>–10<sup>7</sup> K. New spectra could further test these theories (J. Cassinelli, University of California, Berkeley). The solar extreme-ultraviolet spectrum, which gives a good indication of what might be expected from cool main-sequence stars, has been extensively observed at high spectral and spatial resolution, and many spectroscopic diagnostic techniques for measuring electron densities and temperatures have been tested (G.A. Doschek, US Naval Research Laboratory).

Similar spectra of nearby cool stars would allow emission lines formed in the temperature range 2 × 10<sup>4</sup>–10<sup>6</sup> K to be observed, leading to improved models of the structure and energy balance in stellar coronae (C. J.). At present, only average temperatures and densities can be found for stellar coronae, using broad-band X-ray measurements. Spectra and observations of the temporal variation of lines formed at different temperatures would allow more precise determination of coronal conditions and of the contribution made by stellar active regions. It is important to improve measurements of coronal densities and temperatures in order to

\*Berkeley Colloquium on Extreme Ultraviolet Astronomy, Berkeley, California, 19-20 January 1989.

understand known correlations between coronal X-ray fluxes, chromospheric line fluxes and stellar rotation rates. These must be controlled ultimately by the non-thermal heating and the energy loss processes. A wide range of more exotic stellar objects, including symbiotic stars, AM Herculis binary stars, and cataclysmic variables, should also provide exciting

new data (A.K. Dupree, S.J. Kenyon and J.C. Raymond, Harvard-Smithsonian Center for Astrophysics; D.Q. Lamb, University of Chicago). □

## A marriage of convenience or necessity?

Jonathan R. Warner

UBIQUITIN, a 76-amino-acid protein, is, as its name implies, ubiquitous in eukaryotic cells (see ref. 1 for a review). A complex enzymatic system attaches it to proteins, usually by peptide bond formation with the  $\epsilon$ -amino of a lysine, either singly or in branched multiple ubiquitin structures. Ubiquitin can be a signal for the protein-degradation system of cells, much as a blaze on a tree serves as a signal for the logger. But in others its embrace is less lethal; it is reversibly attached to the histone H2A without causing its degradation<sup>2</sup>. Its function here is unknown.

Ubiquitin is remarkably conserved through evolution, with a similarity of 96 per cent between yeast<sup>3</sup> and human<sup>4</sup>, and between yeast and *Trypanosoma cruzi*<sup>5</sup>. Even more remarkable is the conservation in the arrangement of the genes encoding ubiquitin, which are found in two basic forms in most organisms (see figure). Class I is a polyubiquitin gene which encodes a polypeptide of up to 100 uninterrupted, tandemly repeated ubiquitins presumably released by proteolysis at the Gly-Met peptide bond that joins the repeats. Class II is a fusion between a single ubiquitin and one of two other sequences, of either 52 or 76–80 predominantly basic amino acids, again remarkably conserved through evolution. In this issue these basic sequences are identified, in the yeast *Saccharomyces cerevisiae* by Finley *et al.*<sup>6</sup> on page 394, and in mammals by Redman and Rechsteiner<sup>7</sup> on page 438, as members of another common group, ribosomal proteins. Finley *et al.*<sup>6</sup> fused antigenic tags to the *UBI1* and the *UBI3* gene products of yeast and find the 52-amino-acid *UBI1* tail in the 60S ribosomal subunits and the 76-amino-acid *UBI3* tail in the 40S subunits. A protein with the amino-terminal sequence of the *UBI3* extension had previously been identified as ribosomal protein S37 (ref. 8). By immunoblotting with antibodies made against a peptide within the mammalian 80-amino-acid extension, Redman *et al.*<sup>7</sup> find the same protein in the 40S subunits

and identify it as mammalian ribosomal protein S27a. Although less conserved through evolution than ubiquitin, yeast S37 and mammalian S27a are similar. Protein sequence data indicate that the ribosomal proteins from both organisms have been cleaved from the ubiquitin moiety without the loss of any amino acids.

By deletion analysis, Finley *et al.*<sup>6</sup> show that the 52-amino-acid ribosomal protein is essential for cell growth, as are all other

eukaryotic ribosomal proteins they tested. It is therefore surprising that cells without the gene encoding ribosomal protein S37 do grow, although poorly. These cells have a severe deficiency of 40S ribosomal subunits, apparently because of a defect in the final processing step(s) in the formation of 18S ribosomal RNA. Does the lack of S37 influence only ribosome assembly, or does it also have some effect on the rate or accuracy of translation?

It is a remarkable finding that the sole source of two ribosomal proteins is derived from ubiquitin fusion genes. But it is truly extraordinary that this arrangement has persisted throughout eukaryotic evolution, even into the freakish trypanosomes. Is ubiquitin dependent on ribosomal proteins or vice versa? Or is there a mutual symbiosis?

Introns are rare in the genes of *S. cerevisiae*, whereas most of the genes encoding ribosomal proteins have a single intron. Although it is not yet clear what selective pressure has maintained introns in the ribosomal protein genes, it is interesting that the members of the duplicate pair, *UBI1* and *UBI2*, each have an intron in the ubiquitin-coding portion of the gene.

Another conserved region of ubiquitin

genes is the heat-shock promoter element<sup>3,5</sup>. In several organisms, including yeast, the polyubiquitin genes are responsive to stress, but the fusion genes are constitutively expressed. In the case of the yeast genes, this is presumably because of the ribosomal protein enhancer elements, UAS<sub>rp</sub>, found upstream of the fusion genes<sup>3</sup> and almost all ribosomal protein genes<sup>10</sup>. The fusion genes provide the main source of ubiquitin during log growth, when ribosome synthesis is active. The polyubiquitin gene, *UBI4*, is derepressed only late in the growth cycle, during nitrogen starvation or after heat shock — all conditions under which ribosomal protein synthesis is repressed. Ubiquitin need not be derived from the fusion genes, however. If ubiquitin sequences are deleted from all the fusion genes, the cell still grows simply by turning on the polyubiquitin gene<sup>8</sup>.

The ubiquitin moiety of *UBI3* is helpful but not essential in the function of ribosomal protein S37. If S37 is expressed from a *UBI3* gene from which the ubiquitin-coding sequences have been deleted, many copies of the mutant gene are needed to replace fully one copy of the *UBI3* gene. One could speculate that the ubiquitin is used as a translational spacer for a very short protein, as a nuclear localization signal or as a 'wedge' to assist in assembling proteins into the ribosome. At what point in the assembly process is the ubiquitin cleaved? An alternative view derives from the observation that the ribosomal proteins turn over very rapidly if not assembled into a ribosome<sup>11,12</sup>. Ubiquitin could protect the ribosomal proteins from degradation, or perhaps cleavage from a ubiquitin molecule is a stratagem to make a protein without an amino-terminal methionine.

Although neither ubiquitin nor ribosomal protein seems essential for the other, there must be some explanation for this ancient and enduring marriage. That explanation may reveal the original role of ubiquitin, or some hitherto unsuspected connection between protein synthesis and protein degradation. □

# Origins of marginal basins

Leg 124 shipboard scientific party\*

THE Sulu and Celebes seas are tectonically critical, but poorly known, marginal basins in the western Pacific Ocean. On Leg 124, completed in early January, we sought to determine the age, stratigraphy, palaeo-oceanography and current state of stress in the basaltic basement of these basins, drilling at five sites (see figure). We discovered unusually fine magnetostratigraphy in the basins, including the documentation of a magnetic reversal event within the Matuyama chron (approximately 1.1 million years (Myr) ago), which has been observed in few locations previously.

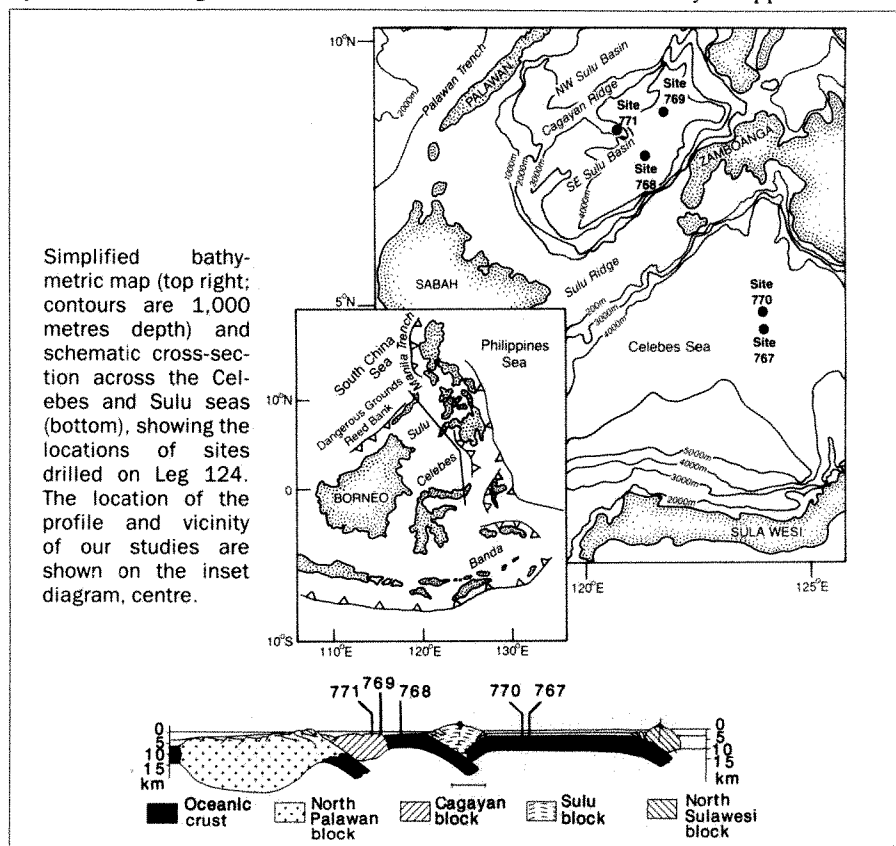

The western Pacific region is characterized by a series of marginal basins bordered by festoons of island arcs. The Sulu, Celebes and Banda basins are thought by some to represent an originally continuous, trapped fragment of a once-larger ocean basin, and by others to have formed by back-arc spreading. Our results rule out a single origin for all the basins, and it seems most likely that the origins of the Celebes and Sulu basins are very different. The basins lie in a broad zone of collisional tectonics, and one of our principal objectives was to use the sedimentary record of the basins to constrain the history of collisional events. Also, stress orientations within the basins establish the primary forces active in this complex zone of collisional tectonics, and the comparison of these results with those from Leg 123 in the south-east Indian Ocean should be instructive.

Basement underlying the Celebes Sea is plagioclase-olivine phyric basalt, and the Sulu Sea basement is composed of olivine basalt. We recovered pillow basalts at both sites in the Celebes Sea — 100 m at site 770 but only 42 cm at site 767. The cores from site 770 include sill and glass-rimmed pillow basalts and intercalated massive, veined flows. We drilled to a depth of 222 m at site 768 in the Sulu Sea basement, recovering a series of pillow basalts and sheet flows, intruded by

two dolerite sills. The trace-element geochemistry of the Celebes Sea basement (site 767) bears the signature of normal mid-ocean ridge basalts (MORB), whereas the Sulu Sea basalts seem to be transitional between MORB and island-arc tholeiites.

The stratigraphies of sediments in the basins yield a detailed record of their histories. The Celebes Sea originated in an open ocean setting in the middle Eocene

as a back-arc or intra-arc basin in the late early to early middle Miocene as determined by radiolarian biostratigraphy in sediments overlying basement. This age coincides with the collision of the Cagayan Ridge with the rifted continental margin of China. Initial deposition of volcanic brown clay was followed shortly thereafter by coarse tuffs from rapidly deposited pyroclastic flows. Slow accumulation rates ( $9 \text{ m Myr}^{-1}$ ) marked the early part of the middle Miocene, but in the late middle Miocene (10.5 Myr ago), very rapidly deposited ( $300 \text{ m Myr}^{-1}$ ) continentally derived turbidites inundated the basin. These volcanic ash layers appeared in the

(42 Myr ago). This age is constrained by the biostratigraphy of clays bearing radiolarians (planktonic protozoa) directly above basement. This determination is consistent with previously determined magnetic anomalies in the basin (Weissel, J.K. *Am. Geophys. Un. Geophys. Monogr.* 23, 37–47; 1980). By the middle Miocene (14 Myr ago) the sea was receiving continentally derived turbidite deposits rich in quartz and plant debris. By the late Miocene (6 Myr ago) nearby explosive arc volcanism was producing thin ash layers in the basin, and continued to provide a major component to the basin sediments until recently. No major carbonate units occur at site 767, but thin carbonate turbidites were deposited sporadically in the middle to late Miocene and more commonly in the Pliocene (5.1–1.6 Myr ago) at this site.

The Sulu Sea seems to have originated

basin 6 Myr ago, indicating the initiation of some of the volcanoes that presumably surround the basin.

A significant change in sediment type from green clay below to nannofossil marl above occurred 1.9 Myr ago, probably indicating the time of rapid shallowing of the surrounding sills, isolating the basin from deep waters of the Pacific. This was also a period of rapid shallowing of the calcite compensation depth worldwide, which could also have contributed to some of the change in sedimentation in the Sulu Sea.

Sites 769 and 771 on the flank of the Cagayan volcanic ridge, penetrated a section similar to that at site 768 in the Sulu Sea, but devoid of turbidites, and therefore very much thinner (280 and 240 m of sediments, respectively). Brown claystone at the base of the section at site 769 contains late early to early middle

Miocene radiolarians, and marl at site 771 contains radiolarians and nannofossils of this age, the same as that of the Sulu Sea and the cessation of volcanism on Cagayan Ridge. We also found volcanic tuffs at site 769 beneath the brown claystone, but these tuffs are basaltic to andesitic in composition, indicating a different source from the rhyolitic to dacitic tuff in the deep Sulu Sea.

Logging at sites 770 and 768 included use of the borehole viewer, which measures the shape and roughness of the hole in the basement. The holes tend to be elliptical, with their long axes lying perpendicular to the direction of maximum horizontal stress. In places the long axes tend to develop small 'breakouts', which are easily visible in the record. The method thus gives a measure of stress direction. Preliminary results at both sites indicate that the maximum horizontal stress direction trends to the north-east, which is consistent with the expected stresses related to the Miocene and Pliocene collisions of the Sulu, Cagayan and Palawan ridges with the Philippine mobile belt.

#### PALAEONTOLOGY

## Sea-dragons all aswim

Michael A. Taylor

THREE major finds of fossil marine reptile on display in a new exhibition\* in Bristol will fuel the current revolution in marine reptile studies. The existence of several different kinds of large predator in the same sea poses difficult questions about their ecological partitioning. Two of the new finds are ichthyosaurs from the Lower Liassic (about 200 million years ago) and the third is the skull of a pliosaur, from the rather younger Kimmeridge Clay of Westbury, Wiltshire, UK (see figure).

A virtually complete skeleton of an ichthyosaur from Charmouth<sup>1</sup> in Dorset, UK was about 9 m long in life. Although comparable in length with other large Liassic ichthyosaurs, its long, delicate snout and tiny, sharp teeth contrast with their robust snouts and heavier teeth. The large size of the Charmouth ichthyosaur combined with a narrow snout suggests a diet of small, abundant prey near the base of the food chain. But marine reptiles never seem to have exploited filter-feeding on even smaller prey, as do the modern mysticete whales, filter-feeding sharks and the newly reinterpreted giant teleost fish *Leedsichthys*<sup>2</sup> from the Jurassic Period.

The only known specimen of the much smaller ichthyosaur *Excalibosaurus costini*<sup>3</sup> is also on display in Bristol. This

A short, normally polarized, full-reversal event within the Matuyama chron is evident in the palaeomagnetic record. Occurring just below the Jaramillo sub-chron 1.1 Myr ago, this reversal corresponds to the Cobb Mountain event documented by E.A. Mankinen *et al.* (*Geology* **6**, 653–656; 1978) and is supported by marine magnetic-anomaly profiles described by D.K. Rea and R.J. Blakely (*Nature* **255**, 126–128; 1975).

Maturity of the terrestrial type of organic matter at Site 768 reaches the stage of thermal hydrocarbon generation at a shallow sub-bottom depth, indicating a thermal gradient greater than 100 °C km<sup>-1</sup>. We even observed some thermogenic generation of gas at this site.

Calcium and magnesium in interstitial waters show positively correlated increases with depth in the lower parts of the sedimentary sections of sites 767–770. Because normal alteration products of basalt scavenge magnesium, these observations suggest the presence of a chemical mechanism of crustal alteration previously unsuspected in the oceanic crust. □

Restoration of the pliosaur *Liopleurodon macromerus*, a 7.5-m-long oceanic predator of 150 million years ago (courtesy of John G. Martin and Bristol City Museum and Art Gallery).

of fast teleost fish has been implicated in the marine reptiles' decline: many had disappeared from the seas long before the end of the Cretaceous period (65 million years ago).
